Field of the Invention

The invention relates to exchanging instructions and/or data between applications to
signal readiness to transfer, exchange, or process data, or to establish at least one or more
15 parameters for transferring data between the applications, and controlling the parameters
in order to facilitate data transfer and communication. The invention further relates to
integrating dissimilar applications one executing within one platform and another
executing in another platform, e.g., multiple computers, multiple operating systems,
multiple application components, multiple development environments, multiple
20 deployment environments, or multiple testing and processing, establishing a dialog (e.g.,
a negotiation) with one another in order to establish connectivity for transferring data
and/or instructions between the applications so as to facilitate performing tasks on the
data or portions thereof to accomplish an overall goal. The parameters may include one
or more of format, data types, data structures, or commands.

25

Background

2

The growth of e-business has created a significant need to integrate legacy applications and bring them to the Internet This is because the current trend for new applications is to embrace Web standards that simplify end user application construction and scalability. Moreover, as new applications are created, it is crucial to seamlessly integrate them with existing systems while facilitating the introduction of new business processes and paradigms.

Integrating new applications with existing applications is especially critical since industry analysts estimate that more than seventy percent of corporate data, including data highly relevant to e-commerce, lives on mainframe computers. Moreover, while many e-commerce transactions are initiated on Windows, Mac, and Linux end user platforms, using a variety of Web browsers, and go through Windows NT and Unix servers, they are ultimately completed on mainframe computers, running mainframe applications, and impacting data stored in mainframe databases.

There are e-business pressures to integrate server level applications and bring them to the Internet. However, there is no complete and easy mechanism to integrate or e-business enable the applications. Integration, whether through messaging, procedure calls, or database queries, is key to solving many of today's business problems.

Integrating legacy applications with new software is a difficult and expensive task due, in large part, to the need to customize each connection that ties together two disparate applications. There is no single mechanism to describe how one application may allow itself to be invoked by another.

One consequence is an e-commerce environment of multiple applications, developed by multiple development teams, running on different platforms, with different data types, data structures, commands, and command syntax's. This environment is stitched together with application program interfaces and connectors. Connectors are an essential part of the total application framework for e-commerce. Connectors match interface requirements of disparate applications and map between disparate interfaces.

3

This growing interconnection of old and new software systems and applications, has led to various middle ware applications and connector applications, interface specifications, interface definitions, and code, especially for the interconnection and interaction of

5   markup languages (such as HTML, XML, Dynamic HTML, WML, and the like), through object oriented languages such as SmallTalk and C++, with languages of legacy application server applications (such as COBOL). These interface specifications, definitions, and code should apply across languages, tools, applications, operating systems, and networks so that an end user experiences the look, feel, and responses of a

10   single, seamless application at her terminal. Instead, the proliferation of standards, protocols, specifications, definitions, and code, e.g., Common Object Request Broker (CORBA), Common Object Model (COM), Object Linking and Embedding (OLE), SOM, ORB Plus, Object Broker, Orbix, has instead created an e-commerce "Tower of Babel."

15

Examples of application integration are ubiquitous: from installing an ERP system, to updating an Operational Data Store (ODS) with IMS transactions or invoking CRM systems from MQSeries; each of these requires the same basic steps. First, a user must find the entity she wants to communicate with, then she must figure out how to invoke

20   the entity, and finally she must provide translation from one native representation to another. Today, these steps usually require manual investigation and hand coding - and leave the developers with a rat's-nest of hard-to-maintain connections between applications.

25   Attempts to remedy this situation involve application program interfaces and connectors, which are frequently built on Interface Definition Languages. Interface Definition Languages are declarative, defining application program interfaces, and, in some cases, issues such as error handling. Most Interface Definition Languages are a subset of C++, and specify a component's attributes, the parent classes that it inherits from, the

30   exceptions that it raises, the typed events that it emits, the methods its interface supports, input and output parameters, and data types. The goal of Interface Definition Languages

4

within connectors is to enable collaboration between dissimilar applications without hard coded application program interfaces.

Ideally, the interface definition language, and the connector of which it is a part, should facilitate full run-time software application collaboration through such features as

- Method invocation with strong type checking,
- Run-time method invocation with greater flexibility and run time binding,
- High level language binding, with the interface separated from the implementation.
- An interface repository containing real time information of server functions and parameters.

Additionally, the connector and its interface definition language, should be fast, efficient, scalable, portable, support metaclasses, support syntactic level extensions, and support semantic level extensions.

Summary of the Invention

The problems associated with integrating new applications, for example, e-commerce applications, with legacy applications are obviated by the Common Application Metamodel tool, method, and system described herein. The Common Application Metamodel method, tool, and system of the invention facilitate tooling solutions, data translation, and communication and collaboration between dissimilar and disparate applications, as well as full run-time software application collaboration through an interface with the application server interface domain. This is accomplished through metadata interchange information, method invocation with strong type checking, run-time method invocation, run time binding, and high level language binding, with the interface separated from the implementation, and an interface repository containing real time information of client and server interface parameters.

5

Additionally, the tool, method, and system of the invention provide fast, efficient, and scalable interconnectivity independently of any tool or middleware, are reusable and portable, and support metaclasses, syntactic level extensions, and semantic level extensions, and are independent of any particular tool or middleware.

5

The Common Application Metamodel tool, method, and system is especially useful for providing a data transformer that is bi-directional between a client application and a server application, transmitting commands and data both ways between, for example, a Java, HTML, XML, C, or C++ application and a COBOL, PL/I, or High Level

10 Assembler application, or, between an HTML or XML application and a Java, C, or C++ application, or between a Java application and a C or C++ application.

One embodiment of the invention is a method of processing a application request on or between an end user application and one or more application servers. The method

15 comprises the steps of initiating the application request on the end user application in a first language with a first application program, transmitting the application request to the server, and converting the application request from the first language of the first end user application to a language running on the application server. Typically, as described above, the client will be a thin client or a Web browser, the application running on the

20 client will be a Web browser application or a thin client connectivity application, and the language of the client application will be Java, C, C++, or a markup language, as HTML or a derivative of HTML, such as XML or Dynamic HTML or WML, or the like, and the language running on the server may be COBOL, PL/I, HLASM (High Level Assembler) or the like. The invention facilitates transformers which convert the application request

25 from the first language of the end user application to a language running on the application server. After conversion, the converted application request is processed on the application server.

The application processes the request and then sends the response from the application

30 server back to the end user application. Typically, as described above, the application server will be running a COBOL based application, and the client will be a thin client

6

written in Java or C or C++, or a Web browser, running a Web browser application or a thin client connectivity application, in a markup language, as HTML or a derivative of HTML, such as XML or Dynamic HTML, or the like. The invention provides data transformers which convert the response from the language or languages running on the
5   application server or servers to the first language of the first end user application.

The end user application and the application server have at least one data transformer between them. In this way, the steps of (i) converting the request from the first language of the first end user application as a source language to the language running on an
10   application server as a target language, and (ii) converting the response from the language running on the application server, as a subsequent source language, back to the first language of the first end user application, as a subsequent target language, each comprise the steps of invoking type descriptor and language metamodels of respective source and target languages, populating the metamodels with each of the respective source and target
15   languages' data items and types, and converting the source language to the target language.

The end user application is, frequently, a web browser or a thin client. When the end user application is a Web browser, the end user is connected to the application server through
20   a web server. According to a further embodiment of the invention, the web server may comprise the connector, or data transformer. The data transformer integrated with the Web server may directly convert the request, application request, or message from a browser oriented form to an application server language or to an intermediate, business or commerce oriented markup language, such as XML.
25

The CAM metamodel used to construct the converter comprises an invocation metamodel, an application domain interface metamodel, a language metamodel, and a type descriptor metamodel. Exemplary invocation metamodel includes information chosen from the group consisting of message control information, security data,
30   transactional semantics, trace and debug information, pre-condition and post-condition resources, and user data, etc. Exemplary application domain interface metamodel

7

comprises information chosen from input parameter signatures, output parameter signatures, and return types. Application domain interface metamodel uses one or more language metamodels, such as COBOL and PL/I metamodels.

5   The type descriptor metamodel defines physical realizations, storage mapping, data types, data structures, and realization constraints.

The method of the invention is applicable to situations where one of the source or target languages is object oriented, and the other of the target or source languages is not object

10   oriented. In this situation, the language metamodel and the type descriptor metamodel together map encapsulated objects of the object oriented language into code and data of the language that is not object oriented. Additionally, the language metamodel and the type descriptor metamodel maps object inheritances of the object oriented language into references and pointers in the language that is not object oriented. The method of the

15   invention is also applicable to situations where different object oriented languages are running on different platforms, and encapsulated objects of the source language (code and data) are mapped into encapsulated objects of the target language. The method of the invention is also applicable where different procedural languages are running on different platforms or applications and commands and data of the source procedural language are

20   mapped into the target procedural language.

According to the method of the invention, there may be a plurality of applications for vertical (sequential, conditional, or dependent) processing, for horizontal (parallel in time) processing, or both horizontal and vertical processing. This is to support rich

25   transactions to and through multiple hierarchical levels and multiple parallel sequences of processing. This may be the case in business to business transactions drawing upon financial, manufacturing, scheduling, supply, and shipping databases and servers, and utilizing various commercial security instruments.

30   A further aspect of the invention is a client-server processing system having a client, a server, and at least one transformer between the client and one or more servers,

8

A still further aspect of the invention is a processing system configured and controlled to interact with a client application. In this aspect of the invention, the system comprises, a server, and at least one transformer between the server and the client application, where

5   the client has an end user application, and is controlled and configured to initiate a request with the server in a first language with a first application program and to transmit the request through a transformer to the server or servers. The server processes the request in a second software application, using a second language, and returns a response to the client through a transformer.

10

A further aspect of the invention is a groupware system having a plurality of e-mail enabled end user applications, such as e-mail, word processing, spreadsheet, simple database management (such as Lotus Approach or Microsoft Access), graphics and graphics editing, audio and audio editing, and computer-telephony integration ("CTI"),

15   along with client level content database client services and content replication client services. Groupware integrates these e-mail enabled applications through one or more transformers and application program interfaces with transport services, directory services, and storage services, including content servers and replication servers. The groupware system is configured and controlled to communicate among disparate end user

20   applications, among disparate servers, and between disparate servers and end user applications. The groupware system comprises at least one transformer between a server and an end user application. The end user application is controlled and configured to participate with a server in a first language of a first application program and the server is configured and controlled to participate with the client in a second language of a second

25   program.

The transformer is configured and controlled to receive a request from the end user application, and convert the request from the first language of the first end user application to a language running on the server. The server is configured and controlled

30   to receive the converted request from the transformer and process the request in a second

9

language with a second application program residing on the server, and to thereafter transmit a response through a transformer back to the end user application.

A still further embodiment of the invention is the provision of rich transaction processing. Rich transactions are nested transactions that span to, through, and/or across multiple servers. The spanning across nested servers may be horizontal, that is parallel dependent transactions, or vertical, that is, serial dependent transactions. Rich transactions may be long lived, on-going transactions, or complex business-to-business transactions, especially those with multiple dependencies or contingencies, volume and prompt payment discounts, late delivery and late payment penalties, and with financial processing, such as electronic letters of credit, electronic bills of lading, electronic payment guarantees, electronic payment, escrow, security interests in the goods, and the like. In a rich transaction environment, some transaction servers may be positioned as clients with respect to other transactions for certain sub transactions making up the rich transaction.

A still further embodiment of the invention is a tool, that is, a software developer's kit, characterized in that the program product is a storage medium (as a tape, floppy disks, a CD-ROM, or a hard drive or hard drives on one of more computers) having invocation metamodels, application domain interface metamodels, and language metamodels, and computer instructions for building a metamodel repository of source and target language metamodels. The program product also contains computer instructions for building connector stubs from the metamodels. The program product further carries computer instructions to build a transformer.

While the invention has been described in summary form as having a single level of connectors, it is, of course, to be understood that such connectors may be present at various levels in the processing hierarchy, for example between Web Clients and Web servers, between web servers and application servers, between application servers and database servers, and between application servers or database servers or both and various specialized repositories.

10

It is also to be understood, that while the invention has been summarized in terms of individual clients and individual servers, there may be multiple clients, multiple servers, and applications that function as both clients and servers, as exemplified by groupware

5 applications, and there might be multiple parallel lines and/or multiple hierarchical levels of application servers, data servers, and databases, as in systems for rich transactions.

The Figures

10 Various elements of the invention are illustrated in the FIGURES appended hereto.

FIGURE 1 illustrates a system with multiple application components, including a Netscape Internet Explorer browser, Net.Commerce on a Sun Solaris server, Oracle and DB2 on a database server, SAP running on AIX, a CICS 390 server, an IMS 390 server,

15 DB2 and DL/I on a S/390 platform, a Windows 200 client, and Baan running on an HP Unix server.

FIGURE 2 illustrates the roles of message sets, SQL stored procedures, legacy applications, and programming languages as inputs to the metadata repository of the

20 Common Application Metamodel to facilitate enterprise application integration at run time.

FIGURE 3 illustrates that the Common Application Metamodel of the invention consists of three kinds of metamodels, i.e., an invocation metamodel, an application-domain

25 interface metamodel, and a language metamodel. For any given application-domain metamodel it may use one or many language metamodels, and there could be zero or many invocation metamodels.

FIGURE 4 illustrates an IMS OTMA metamodel, with an OTMA Invocation Metamodel,

30 an IMS Transaction Message Metamodel application interface, which could use a COBOL Metamodel, a C Metamodel, or other language metamodels.

11

FIGURE 5 illustrates how a tool can be used to generate an XML document describing application program interface. First, an object model, i.e., a CAM metamodel, is created to capture interface definitions about an application server. Then a tool reads and parses

5   the source definitions of an application program and generates an XML document by retrieving the object model's information from a repository.

FIGURE 6 illustrates a development phase scenario where a Common Application Metamodel Rose file, e.g., a COBOL metamodel, a PL/I metamodel, an MFS metamodel,

10   a BMS model, or the like is read into a toolkit, to generate a DTD and XML schema and Java code for a Rose model. A source file of an application, as a COBOL source file, a PL/I source file, an MFS source file, a BMS source file, or the like, is read into an importer. The importer parses the source code and generates, as output, an XMI instance file, i.e., XML documents, by reading in the Java code of the Rose model of the

15   application source files.

FIGURE 7 illustrates a metamodel for application interfaces, which enables integration of application components into an event based messaging model, including flow models. The flow and messaging middle invokes applications through the application interface.

20   These interfaces are access points to the applications through which all input and output is connected to the middleware. The interfaces are described in terms of the Application Interface Metamodels. Transformation processing according to he metamodel could take place in source/client applications, target applications, or a gateway.

25   FIGURE 8 illustrates the application of the Common Application Metamodel during execution time. As shown, the CAM model facilitates connectivity between a back-end IMS application and a Web file (e.g., SOAP complaint XML documents). This is accomplished by using information captured in the model to perform data transformations from one platform to another in a mixed language environment shown.

30

12

FIGURE 27 illustrates the OTMA prefix metadata model.

FIGURE 28 illustrates the OTMA prefix in control data defined data types.

10   FIGURE 29 illustrates the OTMA prefix in state defined data types.

FIGURE 30 illustrates the OTMA prefix in security defined types.

FIGURE 31 illustrates the IMS Messages primitives in the IMS Metamodel.

15

FIGURE 32 illustrates a High Level Assembly Language (HLASM) metamodel to define data structure semantics which represent connector interfaces. This metamodel is also a MOF Class instance at the M2 level.

20   FIGURE 33 illustrates the associations between the HLASM metamodel with the TDLang base classes which are the TDLangClassifier, the TDLanguageComposedType, and the TDLangElement.

FIGURE 34 illustrates an enumeration of the HLASM usage values in the HLASM
25   Metamodel.

FIGURE 35 illustrates a CICS BMS language metamodel, which is usable by application programs to define data structures which represent connector interfaces.

30   FIGURE 36 illustrates attributes, fields, attribute values, maps, and attributes of the BMSMetamodel.

15

FIGURE 37 illustrates a MFS language metamodel, which is usable by application programs to define data structures which represent connector interfaces.

FIGURE 38 illustrates the associations between the classes of the MFS metamodel.

FIGURE 39 illustrates enumerations of Mode Values, Base Values, LengthTypes, and StringTypeValues for the MFS Metamodel.

FIGURE 40 illustrates a simplified network configuration for a "rich" transaction where, for example, an order is entered at a terminal, and is passed to and through a Web server to a manufacturer's application server. The manufacturer's application server searches through it's own database server, as well as its vendors' dissimilar and incompatible database servers and databases, transparently connected by the connectors described herein, querying for statuses, prices, and delivery dates, of components, and placing orders for needed components to satisfy the order.

FIGURE 41 illustrates a group ware session spread across multiple group ware applications running on multiple, disparate platforms, and connected using the common application metamodel described herein.

FIGURE 42 illustrates a commercial transaction where real goods are shipped from a seller to a buyer, and various forms of electronic payment and secured electronic payment are used by the buyer to pay the seller, with banks and financial institutions connected using the common application metamodel described herein.

Detailed Description of the Invention

Definitions. As used herein the following terms have the indicated meanings. "Handshaking" is the exchange of information between two applications and the resulting agreement about which languages, capabilities, and protocols to use that precedes each connection.

An "application program interface" (API) is a passive specific method prescribed by a computer operating system or by another application program by which a programmer writing an application program can make requests of the operating system or another

5   application. Exemplary is SAX (Simple API for XML), an connector that allows a programmer to interpret a Web file that uses the Extensible Markup Language, that is, a Web file that describes a collection of data. SAX is an *event-driven* interface. The programmer specifies an event that may happen and, if it does, SAX gets control and handles the situation. SAX works directly with an XML parser.

10

A "connector" as used herein is a dynamic, run-time, interface between platforms that stores the functions and parameters of the target platform or program, and binds with the target platform program in real time.

15   A "stub" is a small program routine that provides static interfaces to servers. Precompiled stubs define how clients invoke corresponding services on the server. The stub substitutes for a longer program on the server, and acts as a local call or a local proxy for the server object. The stub accepts the request and then forwards it (through another program) to the remote procedure. When that procedure has completed its service, it

20   returns the results or other status to the stub which passes it back to the program that made the request. Server services are defined in the stub using an Interface Definition Language ("IDL"). The client has an IDL stub for each server interface that it accesses and includes code to perform marshaling. Server stubs provide static interfaces to each service exported by the server.

25

"CICS" (Customer Information Control System) is the online transaction processing program from IBM that, together with the Common Business Oriented Language programming language, is a set of tools for building customer transaction applications in the world of large enterprise mainframe computing. Using the programming interface

30   provided by CICS to write to customer and other records (orders, inventory figures, customer data, and so forth) in a CICS, a programmer can write programs that

17

communicate with online users and read from a database (usually referred to as "data sets") using CICS facilities rather than IBM's access methods directly. CICS ensures that transactions are completed and, if not, it can undo partly completed transactions so that the integrity of data records is maintained. CICS products are provided for OS/390,

5   UNIX, and Intel PC operating systems. CICS also allows end users to use IBM's Transaction Server to handle e-business transactions from Internet users and forward these to a mainframe server that accesses an existing CICS order and inventory database.

"IMS" (Information Management System) is the system from IBM that, together with

10   IBM's Enterprise Systems Architecture (IMS/ESA) provides a transaction manager and a hierarchical database server.

"MQ" is the MQSeries IBM software family whose components are used to tie together other software applications so that they can work together. This type of application is

15   often known as business integration software or middleware. Functionally, MQSeries provides a communication mechanism between applications on different platforms, an integrator which centralizes and applies business operations rules, and a workflow manager which enables the capture, visualization, and automation of business processes. MQSeries connects different computer systems, at diverse geographical locations, using

20   dissimilar IT infrastructures, so that a seamless operation can be run. IBM's MQSeries supplies communications between applications, and between users and a set of applications on dissimilar systems. Additionally, MQSeries' messaging scheme requires the application that receives a message to confirm receipt. If no confirmation materializes, the message is resent by the MQSeries.

25

"Rose" is an object-oriented Unified Modeling Language (UML) software design tool intended for visual modeling and component construction of enterprise-level software applications. It enables a software designer to visually create (model) the framework for an application by blocking out classes with actors (stick figures), use case elements

30   (ovals), objects (rectangles) and messages/relationships (arrows) in a sequence diagram using drag-and-drop symbols. Rose documents the diagram as it is being constructed

STL920000075US2

and then generates code in the designer's choice of C++, Visual Basic, Java, Oracle8, Corba or Data Definition Language.

Common Application Metamodel Overview. The Common Application Metamodel

5   (CAM) brings interconnectivity to the environment illustrated in FIGURE 1. FIGURE 1 illustrates a typical system 101 with multiple application components, including a Netscape Internet Explorer browser 103, Net.Commerce 105 on a Sun Solaris server 107, Oracle 109 and DB2 111 on a database server 113, SAP 115 running on AIX 117, a CICS 390 server 119, an IMS 390 server 121, DB2 123 and DL/I 125 on a S/390 platform 127,

10   a Windows 2000 client 129, and Baan 131 running on an HP Unix server 133. The Common Application Metamodel (CAM) is metadata interchange method, tool, and system for marshaling and applying information needed for accessing enterprise applications, such as in FIGURE 1, in a source language and converting them to a target language. CAM consists of language metamodels and application domain interface

15   metamodels, as shown in FIGURE 2, which illustrates the roles of message sets 203, SQL stored procedures 205, legacy applications 207, and programming languages 209 as inputs to the metadata repository 211 of the Common Application Metamodel to facilitate enterprise application integration 221.

20   Exemplary metamodels include C, C++, Java, COBOL, PL/I, HL Assembler, IMS transaction messages, IMS MFS, CICS BMS, and MQSeries messages models, as shown in FIGURE 3, which illustrates the Common Application Metamodel of the invention, with an invocation metamodel 301, an application-domain interface metamodel 303, and a language metamodel 305.

25

FIGURE 4 illustrates an IMS OTMA application interface metamodel 411, with an OTMA Invocation Metamodel 421, an IMS Transaction Message Metamodel 423, a COBOL Metamodel 425, and a C Metamodel 427.

30   FIGURE 5 illustrates the flow of information from an existing application 501, through an interface 503 to an object model containing application interface metadata. This

19

application interface metamodel is stored in the metadata repository 505, and, at an appropriate time, retrieved from the metadata repository 505, combined with a source program 507 in a generation tool 509, and used to generate a target file 511, as an XML file, i.e., an XMI instance file. CAM is highly reusable and independent of any particular

5 tool or middleware.

Development Stage. With CAM, tooling can now easily provide solutions to access enterprise applications, e.g. IMS applications. By parsing each source file and generating XML documents based on the CAM model, COBOL copybook, PL/I copybook, MFS

10 Source, BMS Source, etc., tools can provide connector solutions to IMS, and CICS, etc.

In this regard, FIGURE 6 illustrates a development phase scenario where a Common Application Metamodel Rose file 601, e.g., a COBOL metamodel, a PL/I metamodel, an MFS metamodel, a BMS model, or the like is read into a toolkit 603, to generate a DTD

15 and schema for a Rose model and Java code for a Rose model 605. A source file of an application 607, as a COBOL source file, a PL/I source file, an MFS source file, a BMS source file, or the like, and the Java code for the Rose model 609 are read into an Importer 611. The importer parses the source code and provides, as output, an XMI instance file 613, i.e., XML documents, of the application source files.

20

FIGURE 7 shows a CAM metamodel for application interfaces. This Figure depicts a runtime connector 701 with invocation and transformation capabilities, interfacing with an existing application program 703 through an interface 705 containing the existing application program's interface definition, in accordance with the application interface

25 metamodel 707. The Application Interface metadata is stored in a metadata repository 709.

The flow and messaging middleware 713 invokes applications 703 through the application interfaces 705. These interfaces 705 are the access points to the applications

30 703 through which all input and output is connected to the middleware 713. The interfaces 705 are described in terms of the Application Interface Metamodel.

STL920000075US2

Transformation processing according to the metamodel could take place in source/client applications, target applications, or a gateway.

Because CAM also provides physical representation of data types and storage mapping to

5   support data transformation in an enterprise application integration environment, it enables Web services for enterprise applications.

At development time CAM captures information that facilitates:

a). connector and/or connector-builder tools,

b). data driven impact analysis for application productivity and quality assurance, and

10   c). viewing of programming language data declarations by developers.

The CAM metamodel files are inputs to toolkits used to generate DTD files, XML schemas, and Java classes which represent the CAM model. Importers parse each source file (e.g. COBOL or PL/I copybook, MFS source, and BMS, etc.), and then generate

15   XML documents (i.e. XML instance files) based on Java classes generated by the XMI/MOF2 toolkit.

Run Time.   At run time CAM provides information which facilitates transformation in an enterprise application integration environment where it provides data type mapping

20   between mixed languages, facilitates data translations from one language and platform domain into another.

FIGURE 8 illustrates the application of the Common Application Metamodel during run time. As shown, SOAP compliant XML documents 803 are received in, for example,

25   IBM WebSphere middleware, 805, which contains an IMSConnector for Java 807, and is in contact with an XML Repository 809, containing the XMI instance files for the CAM model. The IBM WebSphere middleware sends the transformed file to the IMS system 811, which contains an instance of IMS Connect 813 and the IMS transactional application program 815. CAM facilitates connectivity between the back-end IMS

30   application 815 and the Web file (e.g., SOAP compliant XML documents) 803. The CAM accomplishes this by using CAM model information (from repository 809) to

21

perform data transformations from one platform to another in the mixed language environment shown.

Type Descriptor Metamodel. One important feature provided by CAM is the Type
5   Descriptor metamodel. The Type Descriptor metamodel defines the physical realization, storage mapping, and the constraints on the realization (such as justification). This metamodel provides a physical representation of individual fields of a given data structure. When supporting data transformation in an enterprise application integration environment, the model provides data type mapping between mixed languages. It also
10   facilitates data translations from one language and platform domain into another. The metamodel is used for runtime data transformation (or marshaling) with a language-specific metamodel for overall data structures and field names.

1.   Common Application Metamodel for Application Interfaces

15

The interconnection of disparate and dissimilar applications running on different software platforms, as shown in FIGURE 1, with different operating systems, physical platforms, and physical realizations is accomplished through connectors that incorporate the interconnection metadata. Connectors are a central part of the application framework for
20   e-business. The end user demand is to connect to anything interesting as quickly, and as easily, as possible.

A connector is required to match the interface requirements of the adapter and the legacy application. It is also required to map between the two interfaces. Standardized
25   metamodels for application interfaces presented herein allow reuse of information in multiple connector tools. These standardized metamodels not only reduce work to create a connector, but also reduce work needed to develop connector builder tools.

The connectors built using the common application metamodel of our invention provide
30   interoperability with existing applications. The connectors support leveraging and reuse of data and business logic held within existing application systems. The job of a

22

connector is to connect from one application system server "interface" to another. Therefore, an application-domain interface metamodel describes signatures for input and output parameters and return types for a given application system domain (e.g. IMS, MQSeries); it is not for a particular IMS or MQSeries application program. The

5 metamodel contains both syntactic and semantic interface metadata.

1.   a.   End-to-End Connector Usage Using Common Application Metamodel

The Common Application Metamodel (CAM) consists of meta-definitions of message

10 signatures, independent of any particular tool or middleware. Different connector builder tools can use this information to ensure the "handshaking" between these application programs, across different tools, languages, and middleware. For example, if you have to invoke a MQSeries application, you would need to build a MQ message using data from a GUI tool and deliver it using the MQ API. Similarly, when you receive a message from

15 the MQSeries application, you would need to get the buffer from MQSeries, parse it and then put it into a GUI tool data structure. These functions can be designed and implemented efficiently by a connector builder tool using CAM as standardized metamodels for application interfaces.

20 CAM can be populated from many sources, including copy books, to generate HTML forms and JavaServer Page (JSP) for gathering inputs and returning outputs. An example of a connector as depicted in the previous figure is that the flow and message middleware makes a function call to an enterprise application by calling the connector which then calls the enterprise application API. The connector does language and data type

25 mappings, for example, to translate between XML documents and COBOL input and output data structures based on CAM. Connectors and CAM provide the end-to-end integration between the middleware and the enterprise applications.

Using IMS as an example. Let's say that you must pass an account number to an IMS

30 transaction application program from your desktop to withdraw $50.00. With CAM and a connector builder tool, you will first generate an input HTML form and an output JSP;

23

and develop a middleware code necessary to support the request. The desktop application fills the request data structure (i.e. an input HTML form) with values and calls the middleware. The middleware service code will take the data from the GUI tool, build an IMS Connect XML-formatted message, and deliver the message to the IMS gateway (i.e.

5   IMS Connect) via TCP/IP. IMS Connect translates between the XML documents and the IMS message data structures in COBOL using the metadata definitions captured in CAM. It then in turn sends the IMS message data structures to IMS via Open Transaction Manager Access (OTMA). The IMS COBOL application program runs, and returns the output message back to the middleware service code via IMS Connect. The middleware

10   service code gets the message and populates the output JSP page (i.e. previously generated GUI tool reply data structures) with the reply data. The transaction output data will then be presented to the user.

2.   Common Application Metamodel

15

CAM is used to describe information needed to easily integrate applications developed in common programming models with other systems. The CAM metamodel can be used for both synchronous and asynchronous invocations.

2.   a.   Common Application Metamodel

20

The common application metamodel depicted as follows consists of an invocation metamodel and an application-domain interface metamodel which uses language metamodels. For any given application-domain interface metamodel, it may use one or

25   many language metamodels, but, there could be zero or more invocation metamodels.

The common connector metamodel is illustrated in FIGURE 3. It has an Invocation Metamodel 301, an Application-Domain Interface Metamodel 303, and a Language Metamodel 305.

30

2.   a.   i.   Invocation Metamodel

24

The invocation metamodel 301 consists of one or more of the following possible metadata elements. However, for a particular invocation, it could include only one or many of the following metadata elements.

5

Message-control information. This includes message control information, such as the message connection name, message type, sequence numbers (if any), and various flags and indicators for response, commit-confirmation, and processing options by which a client or server can control message processing to be synchronous or asynchronous, etc.

10

The connection name can be used by the application system server to associate all input and output with a particular client. The message type specifies that the message is a response message; or that commit is complete. It can also indicate server output data to the client, or client input data to the server.

15

Security data -- This includes authentication mechanism, and security data, e.g. digital certificates, identity, user name and password, etc. It may also include authorization information to indicate whether the data can be authorized via a role based or ACL (access control list) based authorization.

20

Transactional semantics -- This will carry transaction information, e.g. local vs. global transaction; two-phase commit vs. one-phase commit, and transaction context, etc.

Trace and debug -- Trace and debugging information are specified as part of the
25   metamodel.

Precondition and post-condition resource -- This describes application state precondition and post-condition relationships.

30   User data -- This includes any special information required by the client. It can contain any data.

2.   a.   ii.   Application-Domain Interface Metamodel

The application-domain interface metamodel 303, as discussed earlier, describes

5   signatures for input and output parameters and return types for application system

domains.

2.   a,   iii.   Language Metamodel

10   The language metamodel 305, e.g. COBOL metamodel, is used by enterprise application

programs to define data structures (semantics) which represent connector interfaces. It is

important to connector tools to show a connector developer the source language, the

target language, and the mapping between the two. The CAM language metamodel also

includes the declaration text in the model which is not editable (i.e. read-only model).

15   Because the connector/adapter developer would probably prefer to see the entire COBOL

data declaration, including comments and any other documentation that would help

him/her understand the business role played by each field in the declaration.

The language metamodel is also to support data driven impact analysis for application

20   productivity and quality assurance. (But, it is not the intention of the CAM to support

reproduction of copybooks.)

The language metamodels describing connector data are listed as follows:

25   * C

* C++

* COBOL

* PL/I

30   ### 2.   a.   iv.   Type Descriptor Metamodel

The Type Descriptor metamodel is language neutral and defines the physical realization, storage mapping and the constraints on the realization such as justification. This metamodel provides physical representation of individual fields of a given data structure. The type descriptor metamodel is to support data transformation in an enterprise

5   application integration environment to provide data types mapping between mix languages. It also facilitates data translations from one language and platform domain into another. This metamodel will be used as a recipe for runtime data transformation (or marshaling) with language specific metamodel for overall data structures and fields names.

10

3.   An Example of Common Connector Metamodel

IMS OTMA (Open Transaction Manager Access) is a transaction-based, connectionless client/server protocol within an OS/390 sysplex environment. An IMS OTMA transaction

15   message consists of an OTMA prefix, plus message segments for input and output requests. Both input and output message segments contain llzz (i.e. length of the segment and reserved field), and application data. Only the very first input message segment will contain transaction code in front of the application data. IMS transaction application programs can be written in a variety of languages, e.g. COBOL, PL/I, C, and Java, etc.

20   Therefore, the application data can be in any one of these languages.

As shown in FIGURE 4, an IMS OTMA connector metamodel 401 is composed of an invocation metamodel 403 and an IMS transaction message metamodel 405, as well as a COBOL metamodel 407 and a C metamodel 409. As depicted in FIGURE 4, the

25   invocation metamodel 401 is the OTMA prefix, and the IMS transaction message metamodel 405 is the application-domain interface metamodel for the IMS application system which uses language metamodels. Metamodels for COBOL 407 and C 409 are shown.

30   **4.   Type Descriptor Metamodel**

27

The type descriptor metamodel presents a language and platform independent way of describing implementation types, including arrays and structured types. This information is needed for marshaling and for connectors, which have to transform data from one language and platform domain into another. Inspections of the type model for different

5   languages can determine the conformance possibilities for the language types. For example, a long type in Java is often identical to a binary type (computational-5) in COBOL, and if so, the types may be inter-converted without side effect. On the other hand, an alphanumeric type in COBOL is fixed in size and if mapped to a Java type, loses this property. When converted back from Java to COBOL, the COBOL truncation rules

10   may not apply, resulting in computation anomalies. In addition, tools that mix languages in a server environment (e.g., Java and COBOL in CICS and IMS) should find it useful as a way to determine how faithfully one language can represent the types of another.

Therefore, an instance of the type descriptor metamodel describes the physical

15   representation of a specific data type for a particular platform and compiler.

4.   a.   TDLang Metamodel

The TDLang metamodel serves as base classes to CAM language metamodels by

20   providing a layer of abstraction between the Type Descriptor metamodel and any CAM language metamodel. All TDLang classes are abstract and common to all the CAM language metamodels. All associations between TDLang classes are marked as "volatile," "transient," or "derived" to reflect that the association is derived from the language metamodel.   The TDLang model does not provide any function on its own, but it is the

25   type target for the association from the Type Descriptor metamodel to the language metamodels.

FIGURE 9 illustrates the structure of the TDLang Metamodel, with the TDLangClassifier 501, the TDLangComposedType 503 and the TDLangElement 505.

30

28

With the TDLang base classes, the Type Descriptor metamodel can be used as a recipe for runtime data transformation (or marshaling) with the language-specific metamodel for overall data structures and field names, without duplicating the aggregation associations present in the language model.

5

4.   b.   Type Descriptor Metamodel

This metamodel is a MOF Class instance at the M2 level. FIGURE 10 shows the relationships within the type descriptor Metamodel, including the PlatformCompilerType

10   601, the InstanceTDBase 603, the ArrayTD 605, the AggregateInstanceTD 607, the Simple InstanceTD 609, and the InstanceType 611. The InstanceType 611 comprises definitions of the StringTD 613, the AddressTD 615, the NumberTD 617, and the FloatTD 619. FIGURE 11 illustrates a higher level view of the TDLanguageElement and the PlatformCompilerType 601. FIGURE 12 illustrates enumerations of signCoding

15   801, lengthEncoding 803, floatType 805, accessor 807, packedDecimalSign 809, and bitModePad 811.

4.   c.   Type Descriptor and Language models

20   The Type Descriptor model is attached to the CAM Language model by a navigable association between TDLangElement and InstanceTDBase. TDLangElement is the base language model type used to represent a declared data item, i.e., an instance of a type. InstanceTDBase is the base Type Descriptor model type used to represent the implementation-specific instance of this same declared data item. InstanceTDBase is

25   abstract; only one of its subtypes may be instantiated.

It is possible that a data item declared in a programming language may have different implementations. These differences are induced by hardware platform, system platform, and compiler differences. This possibility is modeled by the PlatformCompilerType

30   model type. The association between TDLangElement and PlatformCompilerType is many to one, and the association between PlatformCompilerType and InstanceTDBase is

29

one to one. To navigate from the language model, it is necessary to know what PlatformCompilerType is to be assumed. It is possible that an implementation, upon importing a model instance, will wish to remove from the model the PlatformCompilerType instances that are not of interest.

5

The association between TDLangElement and InstanceTDBase is modeled in this manner to allow for extending the model to include an association between PlatformCompilerType and a new type that more fully describes the hardware platform, the system platform, and the compiler.

10

Data element instances may be defined as repeating groups or arrays. This is modeled as a one to many association between InstanceTDBase and the ArrayTD model type. There would be one ArrayTD instance in this association for each dimension, subscript, or independent index of the data element. These instances hold information about the

15   bounds and accessing computations.

The association is ordered in the same order as the corresponding association in the language model, and reflects the syntactic ordering of the indices as defined by the programming language. The rationale for this choice is the resulting equivalence of navigation and processing algorithms between the language model and the Type

20   Descriptor model. Another choice, perhaps more advantageous to marshaling engines, would be to have the ordering of the indices from the smallest stride to the largest. This allows a marshaling engine to process the array in its natural storage order, assuming it is laid out in the usual contiguous fashion. A marshaling engine can compute this order by re-sorting the association targets according to the stride formulas if desired.

25

Array information may be a complex property of the data element or of its type, and various languages and programming practices seem to fall on either side. The typedef facility of C and C++ allows the definition of some array types from typedefs, but only where the array definitions are applied to the topmost elements of typedef aggregates. For

30   example, consider the following typedef:

```
typedef struct {
        int A;
        struct {
                int C;
                char D;
                struct {
                        int F;
                        int G;
                } E;
        } B;
} X;
```

This typedef can be used to create a new typedef for a fixed size array, e.g.

```
typedef X Q[10];
```

But it is not possible to create a new typedef from X that makes any of the subcomponents of X, e.g., D or E, into an array. This example and many others point out the unclear status of array definitions in typed languages.

An InstanceTDBase type has two concrete subtypes, SimpleInstanceTD and AggregateInstanceTD. SimpleInstanceTD models data elements without subcomponents, while AggregateInstanceTD models data elements with subcomponents. To find the subcomponents of an AggregateInstanceTD, one must navigate back to the corresponding data element declaration in the CAM language model. There, the association between an aggregate type and its subcomponents may be navigated, leading to a set of subcomponent data elements, each of which has one or more corresponding instances in the Type Descriptor model. This introduces some model navigation complexity, but avoids duplicating the aggregation hierarchy in both the language and the Type Descriptor models. The additional processing complexity of traversal is not great, and considerable simplification is obtained in algorithms that would modify the model to add, delete or rearrange subcomponents in an aggregation.

A SimpleInstanceTD model type is also associated one to one with a BaseTD model type. The BaseTD model type is specialized to hold implementation information that is

31

common for all data elements of the same language type. The information that describes a 32-bit signed binary integer on a specific hardware/software platform is thus instantiated only once in a given model instantiation, no matter how many data elements may be declared with this type.

5

One may contemplate an association between TDLangClassifier and BaseTD matching the association between TDLangElement and InstanceTDBase. However, this is problematic in that constructions that the language regards as simple types (e.g., strings) may not map directly to simple hardware/software types. Rather than introduce more mechanisms into the Type Descriptor model to describe string implementations, a specialization of BaseTD is utilized which describes the common string implementations. Various attributes in the TypeDescriptor model are suffixed with the string "formula." These attributes contain information that may in some cases be impossible to compute without access to data created only at run-time. An example is the current upper bound of a variable-sized array or the offset to an element that follows another element whose size is only known at run-time. Such information could be included as values in a model instance, but this would require a model instance for each run-time instance, and would mean that the model could only be constructed at run-time, requiring the model definition to include factories and other apparatus to create model instances at run-time. A model that can be constructed from platform and compiler knowledge is much more useful, and the formulas provide a way to define concrete values when the run-time information is available. These formulas may be interpreted by marshaling engines, or they may be used to generate marshaling code, which is loaded and executed by the marshaling engine on demand.

25

4.   d.   Formulas

As used in connection with formulas, "field" refers to a component of a language data structure described by the Type Descriptor model, while "attribute" denotes part of the model, and has a value representing a "property" of the field. Thus the value of a field means a run-time value in a particular instance of a language data structure, whereas the

32

value of an attribute is part of the description of a field in a language data structure, applies to all instances of the data structure, and is determined when the data structure is modeled.

5   For most attributes in an instance of the Type Descriptor model, the value of the attribute is known when the instance is built, because the properties of the fields being described, such as size and offset within the data structure, are invariant. But if a field in a data structure is defined using the COBOL OCCURS DEPENDING ON construct or the PL/I Refer construct, then some properties of the field (and properties of other fields that

10   depend on that field's value) cannot be determined when the model instance is built.

Properties that can be defined using these language constructs are string lengths and array bounds. A property that could indirectly depend on these language constructs is the offset of a field within a structure, if the field follows a variable-size field.

15

In order to handle these language constructs, properties of a field that could depend on these constructs (and thus the values of the corresponding attributes), are defined with strings that specify a formula that can be evaluated when the model is used.

20   However, if a property of a field is known when the model instance is built, then the attribute formula simply specifies an integer value. For example, if a string has length 17, then the formula for its length is "17".

The formulas mentioned above are limited to the following:

25   * Unsigned integers
     * The following arithmetic integer functions

$$neg(x) := -x \qquad // \text{ prefix negate}$$
$$add(x,y) := x+y \qquad // \text{ infix add}$$
$$sub(x,y) := x-y \qquad // \text{ infix subtract}$$
30   $$mpy(x,y) := x*y \qquad // \text{ infix multiply}$$
$$div(x,y) := x/y \qquad // \text{ infix divide}$$
$$max(x,y) := max(x,y)$$
$$min(x,y) := min(x,y)$$

33

$$mod(x,y) := x \ mod \ y$$

The mod function is defined as mod(x,y) = r where r is the smallest non-negative integer such that x-r is evenly divisible by y. So mod(7,4) is 3, but mod(-7,4) is 1. If y is a power

5 of 2, then mod(x,y) is equal to the bitwise-and of x and y-1.

* The val function

The val function returns the value of a field described by the model. The val function takes one or more arguments, and the first argument refers to the level-1 data structure

10 containing the field, and must be either:

* the name of a level-1 data structure in the language model

* the integer 1, indicating the level-1 parent of the variable-size field. In this case, the variable-size field and the field that specifies its size are in the same data structure, and so have a common level-1 parent.

15

The subsequent arguments are integers that the specify the ordinal number within its substructure of the (sub)field that should be dereferenced.

By default, COBOL data fields within a structure are not aligned on type-specific

20 boundaries in storage. For example, the "natural" alignment for a four-byte integer is a full-word storage boundary. Such alignment can be specified by using the SYNCHRONIZED clause on the declaration. Otherwise, data fields start immediately after the end of the preceding field in the structure. Since COBOL does not have bit data, fields always start on a whole byte boundary.

25

For PL/I, the situation is more complicated. Alignment is controlled by the Aligned and Unaligned declaration attributes. By contrast with COBOL, most types of data, notably binary or floating-point numbers, are aligned on their natural boundaries by default.

30 **4.   d.   i)   Formula examples**

34

STL920000075US2

4.   d.   i)   a)   COBOL

The examples use the proposed inline comment indicator "*>" from the draft standard. It is not yet legal COBOL usage.

5   1.   Consider the following data description:

```
    *> Field              Offset

    01 Used-Car.          *> "0"
10     02 Summary.        *> "0"
       03 Make pic x(36).   *>   "0"
       03 Model pic x(44).  *>   "36"
       03 VIN pic x(13).    *>   "80"
       03 Color pic x(10).  *>   "93"
15        88 Red value 'Red'.
          88 White value 'White'.
          88 Blue value 'Blue'.
       02 History.        *>   "103"
       03 Mileage pic 9(6).     *>   "103"
20     03 NumClaims binary pic 9.   *>   "109"
       03 InsCode pic x.      *>   "111"
       03 Claims.          *>   "112"
          04 Claim occurs 1 to 9 times
             depending on NumClaims.   *> stride(1) = "157"
25           05 ClaimNo pic x(12).
             05 ClaimAmt binary pic 9(5).
             05 Insurer pic x(38).
             05 Details pic x(100).
       02 Price comp pic 9(5)v99.    *>   "add(112,mpy(val(1,2,2),157))"
30
```

The offset of *Model* is straightforward, and is given by the formula *"36"*. So is that of *Claims*, which is *"112"*.

But because the array *Claim* can occur a variable number of times, the structure History

35   is a variable-size field. Thus the offset of *Price*, which immediately follows *Claims*, requires a more complicated formula, involving the array stride (the distance between successive elements along a specific dimension). For *Claim*, there is only one dimension, and the formula for its stride is "154". Thus the formula for the offset of *Price* is:

"add(112,mpy(val(1,2,2),154))"

STL920000075US2

The first argument of the val function is 1, meaning that the field containing the value at run-time, *NumClaims*, is in the same level-1 structure, *Used-Car*, as the field, *Price*, whose offset is specified by the formula. The other two arguments are 2 and 2. The first 2

5 refers to the second immediate subcomponent, *History*, of *Used-Car*. The second 2 means that the field to be dereferenced is the second component of *History*, that is, *NumClaims*.

If the *OCCURS DEPENDING ON* object were in a separate structure, the third

10 subcomponent of level-1 structure *Car-Data*, say, then the val function would be *"val(Car-Data,3)"*.

COBOL structure mapping is top-down, although the direction doesn't make any difference unless the SYNCHRONIZED clause is specified on the data declaration.

15 Specifying SYNCHRONIZED forces alignment of individual fields on their natural boundaries, and thus introduces "gaps" into the structure mapping. Consider the following data structure, which is identical to the previous example, except for the SYNCHRONIZED clause:

```
   *> Field                         Offset

20
   01 Used-Car SYNCHRONIZED     *> "0"
     02 Summary.                *>  "0"
       03 Make pic x(36).       *>   "0"
       03 Model pic x(44).      *>   "36"
25     03 VIN pic x(13).        *>   "80"
       03 Color pic x(10).      *>   "93"
         88 Red value 'Red'.
         88 White value 'White'.
         88 Blue value 'Blue'.
30     02 History.              *>  "103"
       03 Mileage pic 9(6).     *>    "103"
       03 NumClaims binary pic 9.  *>    "110"
       03 InsCode pic x.        *>    "112"
       03 Claims.               *>    "113"
35       04 Claim occurs 1 to 9 times
             depending on NumClaims.  *> stride(1) = "160"
           05 ClaimNo pic x(14).
```

05 ClaimAmt binary pic 9(5).
05 Insurer pic x(39).
05 Details pic x(100).
02 Price comp pic 9(5)v99.   *>
5   *"add(add(113,mpy(val(1,2,2),160)),3)"*

To position the binary fields on their appropriate half-word or full-word storage

boundaries, COBOL introduces padding, known as "slack bytes", into the structure.

Working top-down, this padding is introduced immediately before the field needing

10   alignment. So there is one byte of padding between *Mileage* and *NumClaims*.

For an array, such as Claim, COBOL not only adjusts the padding within an element, but

also the alignment of each element of the array. In the example, the first occurrence of

Claim starts one byte past a full-word boundary. Because the field ClaimNo is an exact

15   number of full-words long, it ends one byte past a full-word boundary, so COBOL inserts

three bytes of padding immediately before the binary full-word integer ClaimAmt. And

to align subsequent occurrences, so that they too start one byte past a full-word boundary

like the first, and can thus have an identical configuration, COBOL adds three bytes of

padding at the end of each occurrence.

20

Finally, after padding, each occurrence of Claim (starts and) ends one byte past a full-

word boundary, so COBOL puts three bytes of padding before the binary field Price. As a

result of all these extra bytes, the formula for the offset of Price has changed considerably

from the unaligned example, and is now:

25   *"add(add(113,mpy(val(1,2,2),160)),3)"*

There are several differences between the OCCURS DEPENDING ON construct and

PL/I's Refer option. Storage for COBOL structures is always allocated at the maximum

size, whereas PL/I structures are allocated at the actual size specified by the Refer option.

30   It is legal and usual to change the number of occurrences in a particular instance of a

variable-size COBOL array, and this has the effect of changing the location and offset of

any fields that follow the array. For PL/I, the value of the Refer object of a particular

instance of a structure is intended to be fixed during execution Thus aligned objects

37

following a variable-size field are always correctly aligned for each instance of the

structure, because the amount of padding is computed uniquely for each instance, as

determined by the Refer option. By contrast, the amount of padding for any aligned fields

following a variable-size COBOL array is computed assuming the maximum array size,

5 and is fixed at compile time. If the array is smaller than its maximum size, then the

alignment will typically be incorrect. For instance in this example:

> *1 a sync.*
> *2 b binary pic 9.*
> *2 c pic x occurs 1 to 5 times depending on b.*
10 > *2 d binary pic 9(9).*

COBOL inserts one byte between c and d. The alignment of d is therefore correct for

only two values of b, the maximum, 5, and 2.

15 As noted above, the formulas describe not only offsets of fields within a structure, but

also properties of arrays, such as bounds and strides. COBOL does not have true multi-

dimensional arrays, although element references do use multiple subscripts. Instead,

COBOL has arrays of arrays, as in the following simple example:

```
20    1 a.                      *< offset = "0"
      2 d1 occurs 5 times.      *< offset = "0"
                                *< lbound(1) = "1"
                                *< hbound(1) = "5"
                                *< stride(1) = "168"
25    3 d2 occurs 6 times.      *< offset = "0"
                                *< lbound(2) = "1"
                                *< hbound(2) = "6"
                                *< stride(2) = "28"
      4 el binary pic 9(9) occurs 7 times.  *< offset = "0"
30                              *< lbound(3) = "1"
                                *< hbound(3) = "7"
                                *< stride(3) = "4"
```

The program can refer to slices of the array by subscripting the higher-level container

35 fields, for example, *d1(2)* or *d2(3, 4)*, but the normal kind of reference is to the low-level

elements using the full sequence of subscripts, for instance, *el(4, 5, 6)*. To locate element

el(m, n, o) using these stride formulas, one would take the address of a and add to it *(m-*

38

1)*168 + (n-1)*28 + (o-1)*4. For COBOL, the lower bound of an array subscript is always 1. That is, the first element is always element(1), and vice versa.

Needless to say, any dimension of the array can have the OCCURS DEPENDING ON clause, and the array can be followed by other fields, which complicates the formulas a lot. Consider the example:

```
1 a.
2 x1 binary pic 9.        *< offset = "0"
2 x2 binary pic 9.        *< offset = "2"
2 x3 binary pic 9.        *< offset = "4"
2 d1 occurs 1 to 5 times  *< offset = "6"
   depending on x1.       *< lbound(1) = "1"
                          *< hbound(1) = "val(1,1)"
                          *< stride(1) = "mpy(val(1,2),mpy(val(1,3),4))"
   3 d2 occurs 1 to 6 times *< offset = "6"
      depending on x2.    *< lbound(2) = "1"
                          *< hbound(2) = "val(1,2)"
                          *< stride(2) = "mpy(val(1,3),4)"
      4 el binary pic 9(9)  *< offset = "6"
         occurs 1 to 7 times *< lbound(3) = "1"
         depending on x3.  *< hbound(3) = "val(1,3)"
                          *< stride(3) = "4"
2 b binary pic 9(5).      *< offset = "see below!"
1
```

Computing the address of a particular element still involves the stride formulas, but these are no longer simple integers. The address of element el(m, n, o) in the above example is given by taking the address of a and adding to it:

(m-1)*stride(1) + (n-1)*stride(2) + (o-1)*stride(3), i.e.,
(m-1)*4*val(1,3)*val(1,2) + (n-1)*4*val(1,3) + (o-1)*4.

Similarly, these stride formulas are used in the formula for the offset of b:

"add(6,mpy(val(1,1),mpy(val(1,2),mpy(4,val(1,3)))))"

4.   d.   i).   b).   PL/I

1.   Given the following structure

```
dcl              /* offset             */
   1 c unaligned    /* "0"               */
    ,2 c1           /* "0"               */
```

```
           ,3 c2   fixed bin(31)      /*    "0"              */
           ,3 c3   fixed bin(31)      /*    "4"              */
           ,2 c4                /*    "8"              */
           ,3 c5   fixed bin(31)      /*    "0"              */
           ,3 c6   fixed bin(31)      /*    "4"              */
           ,3 c7   fixed bin(31)      /*    "8"              */
           ,2 c8   fixed bin(31)      /*    "20"              */
           ,2 c9   char( * refer(c7) ) /*    "24"              */
           ,2 c10  char(6)            /*    "add(24,val(1,2,3))"      */
           ,2 c11  char(4)            /*    "add(add(24,val(1,2,3)),6)" */
        ;
```

The offset of c3 would be given by the simple formula "4", but the offset of c10 would be given by the formula:

```
        "add(24,val(1,2,3))"
```

The first argument in the above val function is 1, which indicates the current structure, c. The subsequent arguments are 2 and 3, indicating that the third element, c7, of the second level-2 field, c4, is the field to be dereferenced.

The offset of c11 is equal to the offset of c10 plus the length of c10 and would be given by the following formula:

```
        "add(add(24,val(1,2,3)),6)"
```

PL/I structure mapping is not top-down, and this can be illustrated by examining the mapping of the following structure:

```
        dcl                    /* offset              */
        1 a based,             /* "0"                 */
          2 b,                 /* "0"                 */
            3 b1 fixed bin(15), /*    "0"             */
            3 b2 fixed bin(15), /*    "2"             */
            3 b3 fixed bin(31), /*    "4"             */
          2 c,                 /* "add(8,mod(neg(val(1,1,1)),4))" */
            3 c1 char( n refer(b1)), /*    "0"        */
            3 c2 fixed bin(31); /*    "val(1,1,1)"    */
```

40

The value of b1 is given by val(1,1,1), and in order to put c2 on a 4-byte boundary, PL/I puts any needed padding before c (yes, not between c1 and c2), and hence the offset of c would be given by the following formula:

"add(8,mod(neg(val(1,1,1)),4))"

5

So if b1 contains the value 3, then this formula becomes add(8,mod(neg(3),4)), which evaluates to 9. I.e., there is one byte of padding between the structure b and the structure c.

10   The model also uses these formulas to specify the bounds and strides in an array, where the stride is defined as the distance between two successive elements in an array.

For example, in the following structure, the second dimension of a.e has a stride specified by the formula "4", and the first dimension by the formula "20":

```
15       dcl
          1 a,                /* offset = "0"      */
            2 b(4) fixed bin(31),    /* offset = "0"      */
                              /* lbound(1) = "1"    */
                              /* hbound(1) = "4"    */
20                            /* stride(1) = "4"    */
            2 c(4) fixed bin(31),    /* offset = "16"     */
                              /* lbound(1) = "1"    */
                              /* hbound(1) = "4"    */
                              /* stride(1) = "4"    */
25          2 d(4) char(7) varying,  /* offset = "32"     */
                              /* lbound(1) = "1"    */
                              /* hbound(1) = "4"    */
                              /* stride(1) = "9"    */
            2 e(4,5) fixed bin(31);  /* offset = "68"     */
30                            /* lbound(1) = "1"    */
                              /* hbound(1) = "4"    */
                              /* stride(1) = "20"   */
                              /* lbound(2) = "1"    */
                              /* hbound(2) = "5"    */
35                            /* stride(1) = "4"    */
```

This means that to locate the element a.e(m,n), one would take the address of a.e and add to it $(m-1)*20 + (n-1)*4.$

41

If the example were changed slightly to:

```
      dcl
5       1 a(4),              /* offset = "0"      */
                             /* lbound(1) = "1"   */
                             /* hbound(1) = "4"   */
                             /* stride(1) = "40"  */
          2 b fixed bin(31),     /* offset = "0"      */
10        2 c fixed bin(31),     /* offset = "4"      */
          2 d char(7) varying,   /* offset = "8"      */
          2 e(5) fixed bin(31);  /* offset = "20"     */
                             /* lbound(1) = "1"   */
                             /* hbound(1) = "5"   */
15                           /* stride(1) = "4"   */
```

then there is padding between d and e, but the user of the type descriptor can be blissfully unaware and simply use the stride and offset formulas to locate any given array element.

The stride for a is "40", the stride for e is "4", and the offset for e is "20". This means that to locate the element a(m).e(n), one would take the address of a and add to it $(m-1)*40 + 20 + (n-1)*4$.

Finally, if the example were changed again to:

```
25    dcl
        1 a(4),              /* offset = "0"      */
                             /* lbound(1) = "1"   */
                             /* hbound(1) = "4"   */
                             /* stride(1) = "40"  */
30        2 b fixed bin(31),     /* offset = "0"      */
          2 c(8) bit(4),         /* offset = "4"      */
                             /* lbound(1) = "1"   */
                             /* hbound(1) = "8"   */
                             /* stride(1) = "4"   */
35        2 d char(7) varying,   /* offset = "8"      */
          2 e(5) fixed bin(31);  /* offset = "20"     */
                             /* lbound(1) = "1"   */
                             /* hbound(1) = "5"   */
                             /* stride(1) = "4"   */
40
```

42

then the computations for a.e are the same as above, but the computations for a.c become interesting.

The stride for a is still "40", the stride for c is "4" (but this "4" is a count of bits, not bytes), and the byte offset for c is "4". To locate the element a(m).c(n), one needs both a byte address and a bit offset. For the byte address, one would take the address of a and add to it (m-1)*40 + 4 + ((n-1)*4)/8. The bit offset of a(m).c(n) would be given by mod((n-1)*4,8).

4.   e.   Type Descriptor Specification

4.   e.   i.   TDLang Metamodel Specification

TDLang Classes - General Overview.   TDLang classes serve as a layer of abstraction between any CAM language model and the TypeDescriptor model.

Since any CAM language model can plug into the TDLang model, the Type Descriptor model only needs to understand how to interface with TDLang in order to access any CAM language model.

The TDLang model does not provide any function on its own and therefore only makes sense when it is attached to a language model. TDLang is common to all the CAM language models and is the type target for the association from TypeDescriptors to the language models.

Note all TDLang classes are abstract and they serve as the base classes to the language metamodels.

TDLangClassifier. TDLangClassifier is the parent class of all language-specific Classifier classes and TDLangComposedType. The TDLangSharedType association is derived from the language's "+sharedType" association from Element to Classifer class.

The association should be marked "volatile," "transient," or "derived" to reflect that the association is derived from the language model. The TDLangClassifier is derived from TDLangModelElement

5   TDLangElement. TDLangElement is the parent class of all language-specific Element classes. The tdLangTypedElement association is derived from the language's "+typedElement" association from Classifer to Element class. The association should be marked "volatile", "transient", and "derived" to reflect that the association is derived from the language model.

10

The tdLangElement association is derived from the language's "+element" association from Classifer to Element class. The association should be marked "volatile," "transient," or "derived" to reflect that the association is derived from the language model.

15

TDLangComposedType. The TDLangComposedType is the parent class of all language-specific ComposedTypes. The TDLangGroup association is derived from the language's "+group" association from Element to ComposedType class. The association should be marked "volatile," "transient," or "derived" to reflect that the association is

20   derived from the language model. The TDLangComposedType is derived from TDLangClassifier.

4.   e.   ii.   Type Descriptor Metamodel Specification

25   The Type Descriptor package defines a model for describing the physical implementation of a data item type. This model is language neutral and can be used to describe the types of many languages. Inspections of the type model for different languages can determine the conformance possibilities for the language types. For example, a long type in Java is often identical to a binary type in COBOL, and if so, the types may be interconverted

30   without side effect. On the other hand, an alphanumeric type in COBOL is fixed in size and if mapped to a Java type, will lose this property. When converted back from Java to

44

COBOL, the COBOL truncation rules may not apply, resulting in computation anomalies.

AggregateInstanceTD. For each instance of an aggregate, there is an instance of this class. To find the children of this aggregate, one must navigate the associations back to language Classifier then downcast to language Composed Type and follow the association to its children.

Derived from InstanceTDBase

Public Attributes:

union : boolean = false

Distinguishes whether the aggregation is inclusive (e.g. a structure) or exclusive (e.g. a union).

If union = true, storage might be overlaid and as a result the interpretation of the content may be uncertain.

ArrayTD. ArrayTD holds information for array types.

Public Attributes:

araryAlign : int

Alignment requirements in addressible units for each element in the array.

strideFormula : string

A formula that can be used to calculate the displacement address of any element in the array, given an index.

strideInBit : boolean

True indicates strideFormula value in bits

False indicates strideFormula value in bytes

upperBoundFormula : String

Declared as a String for instances when this value is referenced by a variable.

This attribute supplies the upperbound value of a variable size array

Upperbound is required when traversing back up the entire structure.

STL920000075US2

lowerBoundFormula : String

Declared as a String for instances when this value is referenced by a variable.

This attribute supplies the lowerbound value of a variable size array.

5   InstanceTDBase.   InstanceTD has instances for each declared variable and structure

element.

To find the parent of any instance (if it has one) one must navigate the associations back

to TDLangElement, follow the association to TDLangClassifier to locate the parent, then

follow the associations back into the TypeDescriptor model.

10   Public Attributes:

offsetFormula : string

A formula for calculating the offset to the start of this instance.

This attribute is String because this field may not always be an integer value. For

15   example, (value(n) + 4) could be a possible value.

NOTE: The offset value is calculated from the top-most parent. (e.g., for a

binary tree A-->B, A-->C, B-->D, B-->E. The offset to D is calculated from A to

D, not B to D)

20   contentSizeFormula : string

Formula for calculating the current size of the contents

allocSizeFormula : string

Formula for calculating the allocated size of the instance

formulaInBit : boolean

25   True indicates offsetFormula, contentSizeFormula, and allocSizeFormula values

are in bits

False indicates offsetFormula, contentSizeFormula, and allocSizeFormula values

are in bytes

defaultEncoding : String

30   Physical encoding - how many bits used to encode code points, how are the code

points mapped onto bit patterns

46

Contains info on how string content is encoded: EBCDIC, ASCII, UNICODE,

UTF-8, UTF-16, codepage numbers, etc...

accessor : enumeration

Specifies access-rights for this element.

5

defaultBigEndian : boolean

True if this element is Big Endian format.

floatType : enumeration

Specifies this element's float type.

10

PlatformCompilerType. A specific data type for a particular platform and compiler.

NOTE: There needs to be some way to identify the platform and compiler. This class can

be specializedor have an attribute, or be simplified by putting an attribute on

InstanceTDBase.

15   Public Attributes:

platformCompilerType : String

This attribute specifies the type of compiler used to create the data in the

language model. Usage of this string is as follows:

"Vendor name, language, OS, hardware platform" (e.g., "IBM, COBOL, OS390,

20   390" or "IBM, PLI, WinNT, Intel")

SimpleInstanceTD. An instance of a Simple type in the language model.

Derived from InstanceTDBase

25   NumberTD

All numbers representations.

Currently includes Integers and Packed Decimals

Note required fields for these types of Numbers:

30

Integer

Base=2

MSBU=0 or 1

Signed/Unsigned

Size (in bytes) = 1,2,4,8 (16)

5

Packed Decimal

Base=10

MSBU=0

Signed

10   Width=1-63

Float

Base=2(IEEE), 16(Hex)

MSBU=0 or 1

15   Signed

Size (in bytes)=4,8,16

Encoding Details...

Derived from BaseTD

20

Public Attributes:

base : int

The base representation of this number. 2=binary, 10=decimal, 16=hex,

...

25   baseWidth : int

Number of bits used to represent base:

e.g. binary = 1, decimal = 8, packed = 4

baseInAddr : int

Number of baseWidth units in addressable storage units - e.g. decimal =

30   1, packed = 2, binary = 8 where the addressable unit is a byte. If the

48

addressable unit was a 32 bit word, decimal would be 4, packed would be 8, and binary would be 32.

baseUnits : int

Number of base units in the number. This times the base width must be

5   less than or equal to the width times the addrUnit.

For example, a 24 bit address right aligned in a 32 bit word would have

base = 1, basewidth=24, baseInAddr=8, width=4.

signCoding : enumeration

A set of enumerations - 2's complement, 1's complement, and sign

10   magnitude for binary; zone signs for decimal, packed signs for packed

decimal, and unsigned binary, unsigned decimal.

checkValidity : boolean

True if language model is required for picture string support

packedDecimalSign : enumeration

15   Used to determine the code point of the sign in COBOL decimal numbers,

where the sign is combined with the leading or trailing numeric digit.

FloatTD

Floating points

20   Derived from BaseTD

Public Attributes:

floatType : enumeration

Specifies this element's float type.

25

1 StringTD

Alphanumeric type

Derived from BaseTD

30   Public Attributes:

encoding : String

Physical encoding - how many bits used to encode code points, how are the code points mapped onto bit patterns

Contains info on how string content is encoded: EBCDIC, ASCII,

5   UNICODE, UTF-8, UTF-16, codepage numbers, etc...

lengthEncoding : enumeration

Possible values for lengthEncoding:

- Fixed length (where total length equals declared string length)

- Length prefixed (where total length equals declared string length plus

10   length of header bytes; usually 1, 2, or 4 bytes)

- Null terminated (known as varyingZ strings in PL/I) (where a null

symbol is added to the end of string; so the maximum length could be up

to declared string length plus one byte to represent null character)

maxLengthFormula : String

15   Formula specifying the maximum length of this string.

checkValidity : boolean

True if language model is required for picture string support

textType : String = Implicit

Value is 'Implicit' or 'Visual'

20   orientation : StringTD = LTR

Value is 'LTR', 'RTL', 'Contextual LTR', or 'Contextual RTL'

where LTR = Left to Right

and RTL = Right to Left

Symmetric : boolean = true

25   True if symmetric swapping is allowed

numeralShapes : String = Nominal

Value is 'Nominal', 'National', or 'Contextual'

textShape : String = Nominal

Value is 'Nominal', 'Shaped', 'Initial', 'Middle', 'Final', or 'Isolated'

30

AddressTD

50

Type to represent pointers/addresses

Rationale for this class:

Addresses should be considered separate from NumberTD class because some languages

on certain machines (e.g., IBM 400) represent addresses with additional information,

5   such as permission type (which is not represented in NumberTD class)

Derived from BaseTD

Public Attributes:

permission : String

10   Specifies the permission for this address. Used primarily for AS/400 systems.

bitModePad : enumeration

Specifies the number of bits for this address. Used to calculate padding.

BaseTD

15   The base class of typeDescriptor.

The BaseTD model type is specialized to hold implementation

information which is common for all data elements of the same language

type. The information which describes a 32 bit signed binary integer on a

20   specific hardware/software platform is thus instantiated only once in a

given model instantiation, no matter how many data elements may be

declared with this type.

Public Attributes:

addrUnit : enumeration

25   Number of bits in storage addressable unit

- bit/byte/word/dword

width : int

Number of addressable storage units in the described type. This can be 1,

30   8, 16, 32 bits.

alignment : int

51

Required alignment of type in address space - e.g. word aligned 32 bit

integer would have alignment of 4

nickname : int

Name of the base element. This should uniquely identify an instance of a

5 simple type to allow logic based on name rather than logic based on

combinations of attributes. E.g. "S390Binary31_0" for a 32 bit S/390

unscaled binary integer

bigEndian : boolean

True if this element is Big Endian format.

10

5.   Language Metamodels

5.   a.   COBOL Metamodel

15   The COBOL metamodel is used by enterprise application programs to define
data structures (semantics) which represent connector interfaces.

FIGURE 13 illustrates a COBOL metamodel to define data structure

semantics which represent connector interfaces. This metamodel is also a

20   MOF Class instance at the M2 level. FIGURE 14 illustrates the associations

between the COBOL metamodel with the TDLang base classes which are the

TDLangClassifier, the TDLanguageComposedType, and the TDLangElement.

FIGURE 15 illustrates an enumeration of the COBOL usage values in the

COBOL Metamodel.

25

The goal of this COBOL model is to capture the information that would be
found in the Data Division. This model is intended to be used only as read-
only to convert COBOL data division into it's XML equivalent. This model is
not intended to be used as a converter from XML code into a COBOL data
30   division equivalent. As a result, initialValues of elements are not captured in
the model.
COBOLSimpleType
COBOLSimpleType is an abstract class that contains attributes shared by
all simple types in the COBOL language.

35

Derived from COBOLClassifier

Public Attributes:

usage : COBOLUsageValues

5   Usage contains the data type as defined in COBOLUsageValues.

Usage defines the format of the data in memory. If none is specified in the
COBOL source, the default is "display". Note that the popular COMP-3 is
equivalent to packed Decimal.

10 pictureString : String

This is a canonical form of the picture string specified in the source. It is
not necessarily identical to the picture string given in the program!
Procedure to arrive at the canonical form of the picture string:
1. Expand any parenthesized characters

15   2. Construct parenthesized representation for any sequences of identical
characters which are longer than 4 characters.
For example:
start with XXX999(3)
after step 1 you get: XXX99999

20   after step 2 you get: XXX9(5)
This canonical form yields the shortest equivalent picture string. The
canonical form is beneficial for equivalence checking.

Synchronized : Boolean = false

This boolean attribute corresponds to the SYNCHRONIZED or SYNC

25   clause that may optionally be specified for an element.
Note that the COBOL language defines an additional clause --
RIGHT/LEFT -- which may follow the SYNCHRONIZED clause.
However, IBM's implementation of COBOL does support this additional
CLAUSE as documentation only -- all elements defined as

30   SYNCHRONIZED are automatically synchronized left.

Public Operations:

getCanonicalPictureString (pictureString : String) : String

35   Returns the condensed value of this string. For example, although the
pictureString attribute may contain a picture string of 9999v99,
getCanonicalPictureString() will return 9(4)v9(2) as the value.

40 COBOLElement

A COBOLElement represents every data definition in the COBOL
program.
For example:
01 EMPLOYEE

45   03 SERIAL-NUMBER PIC 9(5).

55

03 DEPARTMENT PIC (5).

EMPLOYEE, SERIAL-NUMBER, and DEPARTMENT are all
COBOLElements.

Derived from TDLangElement

Public Attributes:
level : String
    Level refers to the data number this element was declared in.
redefined : Boolean = false

COBOLVariableLengthArray
    A COBOLVariableLengthArray should be instantiated whenever the
    source for a COBOLElement has the
    following syntax:
    LEVEL ELEMENTNAME1 OCCURS X1 TO X2 TIMES DEPENDING
    ON ELEMENTNAME2.
    where X1 and X2 can be any integers 0 and higher and
    X2 > X1. ELEMENTNAME2 must be defined before
    ELEMENTNAME1.
    COBOLVariableLengthArray has a single required
    association that specifies which element this array
    depends on.
Derived from COBOLFixedLengthArray

Public Attributes:
minUpper : Integer
    In the case when maxUpper (max upper bound) belongs to VariableArray,
    maxUpper denotes the absolute upper bound of the array that can be
    allocated in memory. The actual maximum is denoted by the value of the
    element it refers to; which it gets by calling the "dependingOn"
    association.

    minUpper (minimum upper bound) is used to capture the COBOL syntax
    that reads OCCURS 4 to 7 TIMES DEPENDING ON X1. In this case,
    minUpper equals 4 and maxUpper equals 7, and the actual upper bound
    depends on the value of X1.

    lower (lower bound) is always 1 (one) in the case of COBOL but is
    included for consistency with other languages and for clarity.

STL920000075US2

COBOLRedefiningElement
The REDEFINES clause allows you to use different data description
entries to describe the same computer storage area.

5 Example of this class in use:
1 TEST
    2 Y PIC X(4)
    2 YR REDEFINES Y BINARY PIC 9(5)

10 TypeDef = False for Redefine/UNION
Derived from COBOLElement

COBOLComposedType
The COBOLComposedType class represents a nested declaration that
15 contains additional elements. COBOLComposedType class is an
aggregate of COBOLElements
COBOLComposedType is also the parent class of COBOLRedefines.

For example:
20 01 STUDENT.
05 CLASSES OCCURS 5.
10 CLASSNAME PIC X(20).
10 CLASSNUM PIC 9(4).

25 STUDENT is defined by COBOLComposedElement. Its aggregation
only point to the CLASSES item, which is a COBOLElement. CLASSES
is itself defined by a COBOLComposedElement.
Derived from COBOLClassifier, TDLangComposedType

30 COBOL88Element
COBOL88Element represents the COBOL 88 data level.
For example:
1 TESTX PIC .
    88 TRUEX VALUE 'T' 't'.   *(TRUEX has 2 values)
35   88 FALSEX VALUE 'F' 'f'.   *(FALSEX has 2 values)

Where TRUEX and FALSEX are condition names for the TESTX variable
if value equals ('T' or 't') or ('F' or 'f'), respectively.
So if TESTX = 'T' or 't' then TRUEX = TRUE and FALSEX = FALSE;
40 If TESTX = 'F' or 'f' then FALSEX = TRUE and TRUEX = FALSE;

Public Attributes:
name : String
Specifies the name or handle of the COBOL88Element.
45

57

COBOL88ElementValue

Example of this class in use:

1 TESTX PIC X.

    88 TRUEX VALUE 'T' 't'.   *(TRUEX has 2 values)

    88 FALSEX VALUE 'F' 'f'.   *(FALSEX has 2 values)

    88 UA VALUE 'A' THRU 'I' 'J' THRU 'R' 'S' THRU 'Z' '&' '-'.

      *UA has 5 values; the first 3 are ranges

Rationale for this class:

-- This class exists because each COBOL88Element can contain more than 1 value. For example, TRUEX contains 2 values, 'T' and 't'. Thus this class can be instatiated more than once (but at least once) per COBOL88Element (and thus the 1...* cardinality)

-- For range values such as 'A' THRU 'I' in UA, lowerLimit = 'A' , upperLimit = 'I', and range = true. Also note that when using the THRU keyword, lowerLimit must be less than upperLimit.

-- For non-range values such as 'T' and 't' we have decided that we would use lowerLimit field to represent the value.

Public Attributes:

lowerLimit : String

    lowerLimit refers to the lower bound of the THROUGH range

upperLimit : String

    upperLimit refers to the upper bound of the THROUGH range

Range : Boolean

    If range is set to true, literal-1 must be less than literal-2, unless the associated data item is a windowed date field.

COBOLAlphaNumericType

The PICTURE character-string must consist of either of the following:

    ·   The symbol

    ·   Combinations of the symbols A, X, and 9 (A character-string containing all As or all 9s does not define an alphanumeric item.)

Other clauses: USAGE DISPLAY must be specified or implied.

Any associated VALUE clause must specify a nonnumeric literal or a figurative constant.

Derived from COBOLSimpleType

Public Attributes:
JustifyRight : Boolean = false
This boolean corresponds to the JUSTIFIED (or JUST) clause. Note that JUST and JUST RIGHT carry the same meaning.

5

COBOLNumericEditedType
The PICTURE character-string can contain the following symbols:
B P V Z 9 0 / , . + - CR DB * cs

10

Other clauses: USAGE DISPLAY must be specified or implied.
Any associated VALUE clause must specify a nonnumeric literal or a figurative constant. The literal is treated exactly as specified; no editing is done.

15

Edited Types are different from non-edited types in that the decimal character is stored in memory for edited types and not stored in non-edited types.
Derived from COBOLSimpleType

20

Public Attributes:
BlankWhenZero : Boolean
This boolean corresponds to the BLANK WHEN ZERO clause.

25 True if BLANK WHEN ZERO.
currencySign : String
This string represents different currency signs used in the world, for example, $, £, DM, etc...
Decimal : Boolean
30 The Decimal boolean exchanges the functions of the peroid and comma in picture strings and numeric values.

If TRUE, decimals are used (e.g., 1,234.56)

35 If FALSE, commas are used (e.g., 1.234,56)

COBOLNumericType
Types of numeric items are:
40 · Binary
· Packed decimal (internal decimal)
· Zoned decimal (external decimal)

The PICTURE character-string can contain only the symbols 9, P, S, and
45 V.

59

For numeric date fields, the PICTURE character-string can contain only the
symbols 9 and S.

5   Examples of valid ranges
                PICTURE   Valid Range of Values

                9999   0 through 9999
                S99   -99 through +99
10   S999V9   -999.9 through +999.9
                PPP999   0 through .000999
                S999PPP   -1000 through -999000 and
                           +1000 through +999000 or zero

15   Other clauses: The USAGE of the item can be DISPLAY, BINARY,
          COMPUTATIONAL, PACKED-DECIMAL, COMPUTATIONAL-3,
          COMPUTATIONAL-4, or
          COMPUTATIONAL-5.

20   Possible usage values for this class are 'binary', 'packedDecimal' and
          'display', which are represented by comp-1 and comp-2 declarations,
          respectively.
          Derived from COBOLSimpleType

25   Public Attributes:
          Signed : Boolean
               This boolean corresponds to the SIGN clause.

               True if number is signed.
30   SignLeading : Boolean
               This attribute corresponds to the LEADING (versus TRAILING) clause.

               True if LEADING.
          SignSeparate : Boolean
35   This boolean corresponds to the SEPARATE clause.

               True is SEPARATE.
          currencySymbol : char
               This character represents the symbol used in COBOL to represent
40   currencySign. (e.g., $=$, L= £, D=DM, etc...)
          trunc : String
               The Trunc option determines whether decimal picture constraints must be
               honored for binary data items.

45   Values for Trunc are:
          STD, OPT, and BIN

TRUNC(STD) conforms to the COBOL 85 Standard, while
TRUNC(OPT) and
TRUNC(BIN) are IBM extensions.

5

For more information on the Trunc attribute, please refer to "COBOL/VSE
Programming Guide"

numproc : String
10   Numproc(PDF) imposes stricter standards on decimal sign values.

Values for Numproc are:
NOPDF, PDF, and MIG.

15   Use NUMPROC(NOPFD) if you want the compiler to perform invalid
sign processing. This option is not as efficient as NUMPROC(PFD);
object code size will be increased, and there may be an increase in run-
time overhead to validate all signed data.

20   NUMPROC(NOPFD) and NUMPROC(MIG) conform to the COBOL 85
Standard.

Decimal : Boolean
The Decimal boolean exchanges the functions of the peroid and comma in
25   picture strings and numeric values.

If TRUE, decimals are used (e.g., 1,234.56)

If FALSE, commas are used (e.g., 1.234,56)
30

COBOL66Element
COBOL66Element represents the COBOL 66 data level.
For example:
35   01 DATA-GROUP PIC 9.
    03 DATA1 VALUE 1.
    03 DATA2 VALUE 2.
    03 DATA3 VALUE 3.
66 SUB-DATA RENAMES DATA1 THROUGH DATA2.
40   66 AKA-DATA3 RENAMES DATA3.

In this example SUB-DATA refers to contents in DATA1 and DATA2.

Public Attributes:
45   name : String
Specifies the name or handle of the COBOL66Element.

61

COBOLFixedLengthArray

A COBOLFixedLengthArray should be instantiated whenever the source for a COBOLElement has the following syntax:

LEVEL ELEMENTNAME OCCURS X TIMES.

where X can be any integer 1 or higher.

In the case when maxUpper (max upper bound) belongs to FixedArray, maxUpper denotes the upper bound of the array that is allocated in memory.

lower (lower bound) is always 1 (one) in the case of COBOL but is included for consistency with other languages and for clarity.

COBOLDBCSType

The PICTURE character-string can contain the symbol(s) G, G and B, or N.

Each G, B or N represents a single DBCS character position.

The entire range of characters for a DBCS literal can be used.

Other clauses: When PICTURE clause symbol G is used, USAGE DISPLAY-1 must
be specified.

When PICTURE clause symbol N is used, USAGE DISPLAY-1 is assumed and does
not need to be specified.

Any associated VALUE clause must specify a DBCS literal or the figurative
constant SPACE/SPACES.

The DBCSType occupies 2 bytes per character.

Derived from COBOLSimpleType

COBOLAlphaNumericEditedType

The PICTURE character-string can contain the following symbols:

A X 9 B 0 /

The string must contain at least one A or X, and at least one B or 0 (zero) or /.

The contents of the item in standard data format must be two or more characters from the character set of the computer.

Other clauses: USAGE DISPLAY must be specified or implied.

Any associated VALUE clause must specify a nonnumeric literal or a figurative constant. The literal is treated exactly as specified; no editing is done.

5 Edited Types are different from non-edited types in that the decimal character is stored in memory for edited types and not stored in non-edited types.
Derived from COBOLSimpleType

10 COBOLClassifier
COBOLClassifier class is the parent class of COBOLComposedType and COBOLSimpleType and contains the 'typedef' attribute.

The best way to think of the effect of TYPEDEFs in COBOL is as lexical
15 substitution, similar to simple C macros. Replace the TYPE clause by everything following the TYPEDEF keyword. Then, after adjusting the level numbers appropriately, the result has to be legal COBOL (except for the adjusted level numbers themselves, which can exceed 49). The actual rules are quite complicated, as you might expect, so rather than describe
20 those, here are some examples:

A simple way of enforcing shop standards for financial data:
Definition:
1 uniform-amount typedef usage comp pic s9(6)v99 synchronized.
25 Reference:
1 account-record.

...
5 prior-balance type uniform-amount.
5 current-balance type to uniform-amount.
30 ...

Derived from TDLangClassifier

Public Attributes:
35 Typedef : boolean
User-defined types are introduced by using the TYPEDEF attribute, and referred to by the TYPE clause. If type is user-defined, 'typedef' = true.

TypeDef = False for Redefine/UNION
40 name : String
Specifies the name or handle of the COBOLClassifier.

COBOLAlphabeticType
45 The PICTURE character-string can contain only the symbol A.

63

The contents of the item in standard data format must consist of any of the letters of the English alphabet and the space character.

Other clauses: USAGE DISPLAY must be specified or implied.

5   Any associated VALUE clause must specify a nonnumeric literal containing only alphabetic characters, SPACE, or a symbolic-character as the value of a figurative constant.

10   Derived from COBOLSimpleType

Public Attributes:
JustifyRight : Boolean = false
        This boolean corresponds to the JUSTIFIED (or JUST) clause. Note that
15   JUST and JUST RIGHT carry the same meaning.

COBOLObjectReferenceType
        The object reference type points to an object declared in COBOL as
20   USAGE IS INDEX OBJECT REFERENCE METACLASS OF class-
        name-1" where class-name-1 is optional

Derived from COBOLSimpleType

25   Public Attributes:
className : String
        Refers to the name of the object this instance refers to.

30   COBOLSourceText
        This class contains the entire source code (including comments) and its
        associated line number.
        Public Attributes:
        source : String
35   fileName : String

COBOLUnicodeType
        The Unicode type reperesents data stored in Unicode format.
40

Derived from COBOLSimpleType

COBOLInternalFloatType

The COBOLInternalFloat type captures the way floating points are represented in memory. For example, the value 123.45 is represented internally as 12345 with the implied decimal marked between 3 and 4.

5

Possible usage values for this class are 'float' and 'double', which are represented by comp-1 and comp-2 declarations, respectively.

Derived from COBOLSimpleType

10   COBOLExternalFloatType

The COBOLExternalFloat type captures the way floating points are displayed to the user. COBOLExternalFloatTypes are the same as COBOLNumericEditedTypes with the exception that the PIC has a +/- sign before the mantissa and the exponent. For example, the value 123.45

15   may be represented in ExternalFloatType as +12345 E -2

Possible usage values for this class are 'binary', 'packedDecimal' and 'display'.

Derived from COBOLSimpleType

20

COBOLAddressingType

COBOLAddressingType is used for index values, pointer values, and procedurePointer values.

25   Possible usage values for this class are 'index', 'pointer', and 'procedurePointer'.

Derived from COBOLSimpleType

COBOLElementInitialValue

30   Derived from TDLangElement

Public Attributes:
initVal : String
valueKind : COBOLInitialValueKind = string_value

5.   b.   PL/I Metamodel

5

The PLI language metamodel is used by enterprise application programs to define data

structures (semantics) which represent connector interfaces. This metamodel is a MOF

Class instance at the M2 level. FIGURE 16 illustrates a PL/I language metamodel, which

is usable by application programs to define data structures which represent connector

10   interfaces. This metamodel is an MOF class instance at the M2 level. FIGURE 17

illustrates the TDLangClassifier, the TDLanguageComposedType, and the

TDLanguageElement for the PL/I Metamodel. FIGURE 18 illustrates enumerations of

Mode Values, Base Values, LengthTypes, and StringTypeValues for the PL/I

Metamodel.

15

5.   b.   i.   PL/I Metamodel Specification

PLI

The PLI language metamodel is used by enterprise application programs to
20   define data structures (semantics) which represent connector interfaces,

This language model for PL/I attempts to describe PL/I declares that have the
storage class of either
PARAMETER, STATIC or BASED. CONTROLLED, AUTOMATIC and
25   DEFINED are not supported.

In the PL/I languages, extents(that is string lengths, area sizes and array
bounds) may, in general, be declared
as constants, as expressions to be evaluated at run-time, as asterisks, or as
30   defined via the REFER option;
however, none of these choices are valid for all storage classes.

Based variables whose extents are not constant and not defined via the
REFER option are excluded
35   from this model, as are parameters whose extents are specified via asterisks.

STL920000075US2

The INITIAL attribute (which is not valid for parameters in any case) will be ignored by the model.

PLISimpleType

PLISimpleType is an abstract class that contains attributes shared by all simple types in the PLI   language.

Derived from PLIClassifier

PLIElement

* A PLIDeclaration represents every data definition in the PLI program.
* For example:
DCL 1 Employee,
    2 Name,
        3 Last char(29),
        3 First char(29),
    2 Deparment char(5);
where Eemployee, Name, Last, First, and Department are all PLI Elements.

ntation.
Derived from TDLangElement

Public Attributes:
level : String

PLIComposedType

PLIComposedType is a collection of member elements that can be structure, unions, or elementary variables and arrays. PLIComposedType has a single aggregation to include all the elements that are a part of this composition.

A structure is a data aggregate whose elements need not have identical attributes. Like an array, the entire tructure is given a name that can be used to refer to the entire aggregate of data. Unlike an array, however, each element of a structure also has a name.

A structure has different levels. At the first level is the structure name called a major structure. At a deeper level are the names of substructures called minor structures. At the deepest are the element names called elementary names. An elementary name in a structure can represent an array, in which case it is not an element variable, but an array variable.

STL920000075US2

The organization of a structure is specified in a DECLARE statement through the use of level numbers preceding the associated names; level numbers must be integers. A major structure name is declared with the level number 1. Minor structures and elementary names are declared with level numbers greater than 1.

The description of a major structure name is terminated by one of the following:

> The declaration of another item with a level number 1
> The declaration of another item with no level number
> A semicolon terminating the DECLARE statement

A delimiter (usually a blank) must separate the level number and its associated name. For example, the items of a payroll can be declared as follows:

```
DECLARE 1 PAYROLL,
        2 NAME,
          3 LAST CHAR(20),
          3 FIRST CHAR(15),
        2 HOURS,
          3 REGULAR FIXED DEC(5,2),
          3 OVERTIME FIXED DEC(5,2),
        2 RATE,
          3 REGULAR FIXED DEC(3,2),
          3 OVERTIME FIXED DEC(3,2);
```

Indentation is only for readability. The statement could be written in a continuous string as DECLARE 1 PAYROLL, 2 NAME, 3 LAST CHAR(20), etc.

PAYROLL is declared as a major structure containing the minor structures NAME, HOURS, and RATE. Each minor structure contains two elementary names. You can refer to the entire structure by the name PAYROLL, or to portions of the structure by the minor structure names. You can refer to an element by referring to an elementary name.

The level numbers you choose for successively deeper levels need not be consecutive. A minor structure at level n contains all the names with level numbers greater than n that lie between that minor structure name and the next name with a level number less than or equal to n. PAYROLL might have been declared as follows:

68

```
DECLARE 1 PAYROLL,
       4 NAME,
          5 LAST CHAR(20),
          5 FIRST CHAR(15),
       2 HOURS,
          6 REGULAR FIXED DEC(5,2),
          5 OVERTIME FIXED DEC(5,2),
       2 RATE,
          3 REGULAR FIXED DEC(3,2),
          3 OVERTIME FIXED DEC(3,2);
```

This declaration results in exactly the same structuring as the previous declaration.
Derived from PLIClassifier, TDLangComposedType

Public Attributes:
Union : Boolean

PLIElementInitialValue
The INITIAL attribute specifies an initial value or values assigned to a variable at the time storage is allocated for it. Only
one initial value can be specified for an element variable. More than one can be specified for an array variable. A
structure or union variable can be initialized only by separate initialization of its elementary names, whether they are
element or array variables. The INITIAL attribute cannot be given to constants, defined data, noncontrolled parameters,
and non-LIMITED static entry variables.

The INITIAL attribute has three forms.

1. The first form, INITIAL, specifies an initial constant, expression, or function reference, for which the value is
   assigned to a variable when storage is allocated to it.

2. The second form, INITIAL CALL, specifies (with the CALL option) that a procedure is invoked to perform
   initialization. The variable is initialized by assignment during the execution of the called routine. (The routine is not
   invoked as a function that returns a value to the point of invocation.)

69

3.The third form, INITIAL TO, specifies that the pointer (or array of pointers) is initialized with the address of the
character string specified in the INITIAL LIST. The string also has the attributes indicated by the TO keyword.

5 **PLIStringType**
a string is a sequence of contiguous characters, bit, cidechars, or graphics
that are treated a a single data item
Derived from PLIComputationalType

10 **PLIIntegerType**
Declared as Fixed Bin. with precision and scale factors. The prcision is
the total number of digits and the scale is the number of digits to the right
of the binary point.

15 Example

DCL bindata BINARY FIXED (7,3)

could be used to present the number 1011.111B that is 7 data bits, 3 of
20 which is to the right of the binary point.
Derived from PLIArithmeticType

Public Attributes:
precision : Integer
25 **scale : Integer**
Signed : Boolean
BigEndian : Boolean = true

30 **PLIFloatType**
has precision = 2A decimal floating-point constant is a mantissa
followed by an exponent. The mantissa is a decimal fixed-point constant.
The exponent is the letter E followed by an optionally signed integer,
which specifies a power of ten. Decimal floating-point constants have a
35 precision (p), where p is the number of digits of the mantissa.
Examples are:

15E-23	has precision = 2
15E23	has precision = 2)
4E-3	has precision = 1
1.96E+07	has precision = 3
438E0	has precision = 3
3141593E-6	has precision = 7

71

.003141593E3   has precision = 9

The last two examples represent the same value (although with different precisions).

The data attributes for declaring decimal floating-point variables are DECIMAL and FLOAT. For example:

DECLARE LIGHT_YEARS DECIMAL FLOAT(5);

LIGHT_YEARS represents decimal floating-point data items with at least 5   decimal digits.

A binary floating-point constant is a mantissa followed by an exponent and the letter B. The mantissa is a binary fixed-point constant. The exponent is the letter E, followed by an optionally signed decimal integer, which specifies a power of two. Binary floating-point constants have a precision (p) where p is the number of binary digits of the mantissa. Examples are:

101101E5B has precision = 6

101.101E2B has precision = 6

11101E-28B has precision = 5

11.01E+42B has precision = 4

The data attributes for declaring binary floating-point variables are BINARY and FLOAT. For example:

DECLARE S BINARY FLOAT (16);

S represents binary floating-point data items with a precision of 16 binary digits.

The default precision is (21). The exponent cannot exceed three decimal digits. Binary floating-point data is stored as normalized hexadecimal

72

floating-point. If the declared precision is less than or equal to (21), short floating-point form is used. If the declared precision is greater than (21) and less than or equal to (53), long floating-point form is used. If the declared precision is greater than (53), extended floating-point form is used.

5

BigEndian : Boolean = true

10

15

PLIPackedType

The data attributes for declaring decimal fixed-point variables are DECIMAL and FIXED. For example:

declare A fixed decimal (5,4);

20

specifies that A represents decimal fixed-point data of 5 digits, 4 of which are to the right of the decimal point.

These two examples:

25

declare B fixed (7,0) decimal;
declare B fixed decimal(7);

both specify that B represents integers of 7 digits.

30

This example

35

declare C fixed (7,-2) decimal;

specifies that C has a scaling factor of -2. This means that C holds 7 digits that range from -9999999*100 to 9999999*100, in increments of 100.

40

This example

declare D decimal fixed real(3,2);

45

73

specifies that D represents fixed-point data of 3 digits, 2 of which are fractional.

5

pictureString : String
20

PLICodedStringType
Derived from PLIStringType

Public Attributes:
25   **type : StringTypeValues**
varying : LengthType

30 **PLIPictureStringType**
A character picture specification describes a fixed-length character data item, with the additional facility of indicating that any position in the data item can only contain characters from certain subsets of the complete set of available characters.

35

A character picture specification is recognized by the occurrence of an A or X picture specification character. The only valid characters in a character picture specification are X, A, and 9. Each of these specifies the presence of one character position in the character value, which can
40   contain the following:

X   Any character of the 256 possible bit combinations represented by the 8-bit byte.

A   Any alphabetic character, #, @, $, or blank.

5

9   Any digit, or blank. (Note that the 9 picture specification character in numeric character specifications is different in that the   corresponding character can only be a digit).

10

When a character value is assigned, or transferred, to a pictured character data item, the particular character in each position is
checked for validity, as specified by the corresponding picture
specification character, and the CONVERSION condition is raised for
an invalid character. (However, if you change the value either via record-oriented transmission or using an alias, there is no checking).
For example:

15

```
DECLARE PART# PICTURE 'AAA99X';
PUT EDIT (PART#) (P'AAA99X');
```

20

The following values are valid for PART#:

25

```
'ABC12M'
'bbb09/'
'XYZb13'
```

30

The following values are not valid for PART# (the invalid characters are underscored):

35

```
'AB123M'
'ABC1/2'
'Mb#A5;'
```

40   Derived from PLIStringType

Public Attributes:
pictureString : String

45

75

PLINonComputationalType

Represents values that are used to control execution of your program. It consists of the following data types--area, entry, label, file, format, pointer, and offset.

5   Derived from PLISimpleType

PLILabelType

A label is a label constant or the value of a label variable.

10   A label constant is a name written as the label prefix of a statement (other than PROCEDURE, ENTRY, PACKAGE, or FORMAT) so that during execution, program-control can be transferred to that statement through a reference to it. In the following line

15   of code, for example, Abcde is a label constant.

Abcde: Miles = Speed*Hours;

20   The labelled statement can be executed either by normal sequential execution of instructions or by using the GO TO statement to transfer control to it from some other point in the program.

25   A label variable can have another label variable or a label constant assigned to it. When such an assignment is made, the environment of the source label is assigned to the target. If you declare a static array of labels to have initial values, the array is treated as nonassignable.

30   A label variable used in a GO TO statement must have as its value a label constant that is used in a block that is active at the time the GO TO is executed. Consider the following example:

35
declare Lbl_x label;
Lbl_a: statement;

.

40
.

.

45   Lbl_b: statement;

76

STL920000075US2

5

·

·

·

Lbl_x = Lbl_a;

10

·

·

·

15   go to Lbl_x;

Lbl_a and Lbl_b are label constants, and Lbl_x is a label variable. By
assigning Lbl_a to Lbl_x, the statement GO TO Lbl_x transfers control to
20   the Lbl_a
statement. Elsewhere, the program can contain a statement assigning
Lbl_b to Lbl_x. Then, any reference to Lbl_x would be the same as a
reference to Lbl_b.
This value of Lbl_x is retained until another value is assigned to it.

25

If a label variable has an invalid value, detection of such an error is not
guaranteed. In the following example, transfer is made to a particular
element of the array Z
based on the value of I.

30
          go to Z(I);

·

35   ·

·

          Z(1): if X = Y then return;

40   ·

·

·

45   ·

77

Z(2): A = A + B + C * D;

.

5   .

.

Z(3): A = A + 10;

10

If Z(2) is omitted, GO TO Z(I) when I=2 raises the ERROR condition. GO
TO Z(I) when I < LBOUND(Z) or I > HBOUND(Z) causes unpredictable
results if the
15   SUBSCRIPTRANGE condition is disabled.
Derived from PLINonComputationalType

PLIFormatType
The remote (or R) format item specifies that the format list in a FORMAT
20   statement is to be used.

The R format item and the specified FORMAT statement must be internal
to the same block, and they must be in the same invocation of that block.

25   A remote FORMAT statement cannot contain an R format item that
references itself as a label-reference, nor can it reference another remote
FORMAT statement that leads to the eferencing of the original FORMAT
statement.

30   Conditions enabled for the GET or PUT statement must also be enabled
for the remote FORMAT statement(s) that are referred to.

If the GET or PUT statement is the single statement of an ON-unit, that
statement is a block, and it cannot contain a remote format item.

35
For example:

```
DECLARE SWITCH LABEL;
GET FILE(IN) LIST(CODE);
40      IF CODE = 1
    THEN SWITCH = L1;
    ELSE SWITCH = L2;
GET FILE(IN) EDIT (W,X,Y,Z)
    (R(SWITCH));
45      L1:  FORMAT (4 F(8,3));
L2:  FORMAT (4 E(12,6));
```

78

SWITCH has been declared to be a label variable; the second GET
statement can be made to operate with either of the two FORMAT
statements.

Data format items describe the character or graphic representation of a
single data item. They are:

A - Character
B - Bit
C - Complex
E - Floating point
F - Fixed point
G - Graphic
P - Picture

The remote format item specifies a label reference whose value is the label
constant of a FORMAT statement located elsewhere. The
FORMAT statement contains the remotely situated format items. The
label reference item is: R.

The first data format item is associated with the first data list item, the
second data format item with the second data list item, and so
on. If a format list contains fewer data format items than there are items in
the associated data list, the format list is reused. If there are
excessive format items, they are ignored.

Suppose a format list contains five data format items and its associated
data list specifies ten items to be transmitted. The sixth item in
the data list is associated with the first data format item, and so forth.
Suppose a format list contains ten data format items and its
associated data list specifies only five items. The sixth through the tenth
format items are ignored.

Example:

    GET EDIT (NAME, DATA, SALARY)(A(N), X(2), A(6), F(6,2));

This example specifies that the first N characters in the stream are treated
as a character string and assigned to NAME. The next 2
characters are skipped. The next 6 are assigned to DATA in character
format. The next 6 characters are considered an optionally
signed decimal fixed-point constant and assigned to SALARY.

79

Derived from PLINonComputationalType

PLIEntryType

Entry data can be an entry constant or the value of an entry variable.

An entry constant is a name written as a label prefix to a PROCEDURE or ENTRY statement, or a name declared with the ENTRY attribute and not the VARIABLE attribute, or the name of a mathematical built-in function.

An entry constant can be assigned to an entry variable. For example:

```
P:  PROCEDURE;
DECLARE EV ENTRY VARIABLE,
   (E1,E2) ENTRY;

EV = E1;
CALL EV;
EV = E2;
CALL EV;
```

P, E1, and E2 are entry constants. EV is an entry variable. The first CALL statement invokes the entry point E1. The second CALL invokes the entry point E2.

The following example contains a subscripted entry reference:

```
DECLARE (A,B,C,D,E) ENTRY,
DECLARE F(5) ENTRY VARIABLE
   INITIAL (A,B,C,D,E);
DO I = 1 TO 5;
CALL F(I) (X,Y,Z);
END;
```

The five entries A, B, C, D, and E are each invoked with the parameters X, Y, and Z.

When an entry constant which is an entry point of an internal procedure is assigned to an entry variable, the assigned value remains valid only for as long as the block that the entry constant was internal to remains active (and, for recursive procedures, current).

ENTRYADDR built-in function and pseudovariable allows you to get or set the address of the entry point of a PROCEDURE or an

80

ENTRY in an entry variable. The address of the entry point is the address of the first instruction that would be executed if the entry were invoked. For example:

5

    PTR1 = ENTRYADDR(ENTRY_VBL);

obtains the address of the entry point, and

10

    ENTRYADDR(ENTRY_VBL) = PTR2;

Derived from PLINonComputationalType

Public Attributes:
Limited : Boolean

15

PLIAreaType

Area variables describe areas of storage that are reserved for the allocation of based variables. This reserved storage can be allocated to, and freed

20   from, based variables by the ALLOCATE and FREE statements. Area variables can have any storage class and must be aligned.

When a based variable is allocated and an area is not specified, the storage is obtained from wherever it is available. Consequently, allocated based

25   variables can be scattered widely throughout main storage. This is not significant for internal operations because items are readily accessed using the pointers. However, if these allocations are transmitted to a data set, the items have to be collected together. Items allocated within an area variable are already collected and can be transmitted or assigned as a unit while

30   still retaining their separate identities.

You might want to identify the locations of based variables within an area variable relative to the start of the area variable. Offset variables are provided for this purpose.

35

An area can be assigned or transmitted complete with its contained allocations; thus, a set of based allocations can be treated as one unit for assignment and input/output while each allocation retains its individual identity.

40

The size of an area is adjustable in the same way as a string length or an array bound and therefore it can be specified by an expression or an asterisk (for a controlled area or parameter) or by a REFER option (for a based area).

45

81

The area size for areas that have the storage classes AUTOMATIC or CONTROLLED is given by an expression whose integer value specifies the number of

5   reserved bytes.

If an area has the BASED attribute, the area size must be an integer unless the area is a member of a based structure and the REFER option is used.

10   The size for areas of static storage class must be specified as an integer.

Examples of AREA declarations are:

DECLARE AREA1 AREA(2000),
15   AREA2 AREA;

In addition to the declared size, an extra 16 bytes of control information precedes the reserved size of an area. The 16 bytes contain such details as
20   the amount of storage in use.

The amount of reserved storage that is actually in use is known as the extent of the area. When an area variable is allocated, it is empty, that is, the area extent is zero. The maximum extent is represented by the area
25   size. Based variables can be allocated and freed within an area at any time during execution, thus varying the extent of an area.

When a based variable is freed, the storage it occupied is available for other allocations. A chain of available storage within an area is
30   maintained; the head of the chain is held within the 16 bytes of control information. Inevitably, as based variables with different storage requirements are allocated and freed, gaps occur in the area when allocations do not fit available spaces. These gaps are included in the extent of the area.

35

No operators, including comparison, can be applied to area variables.
Derived from PLINonComputationalType

PLIPointerType
40   A pointer variable is declared contextually if it appears in the declaration of a based variable, as a locator qualifier, in a BASED attribute, or in the SET option of an ALLOCATE, LOCATE, or READ statement. It can also be declared explicitly.
Derived from PLINonComputationalType

45

82

PLIFileType

The FILE attribute specifies that the associated name is a file constant or file variable.

5

The FILE attribute can be implied for a file constant by any of the file description attributes. A name can be contextually declared as a file constant through its appearance in the FILE option of any input or output statement, or in an ON statement for any input/output condition.
Derived from PLINonComputationalType

10

PLIOffsetType

You might want to identify the locations of based variables within an area variable relative to the start of the area variable. Offset variables are provided for this purpose.

Public Attributes:
BigEndian : Boolean = true

20

PLIAlias

An alias is a type name that can be used wherever an explicit data type is allowed. Using the DEFINE ALIAS statement, you can
define an alias for a collection of data attributes. In this way, you can

25

assign meaningful names to data types and improve the understandability of a program. By defining an alias, you can also provide a shorter notation for a set of data attributes, which can decrease typographical errors.

30

Example

```
define alias Name   char(31) varying;
define alias Salary fixed dec(7);   /* real by default    */
define alias Zip    char(5)         /* nonvarying by default */
```

35

Derived from PLINamedType
Attribute

The attributes that can be specified are any of the attributes for variables

40

that can be returned by a function (for example, those attributes valid in the RETURNS option and attribute). That is, you cannot specify an alias for an array or a structured attribute list. However, you can specify an alias for a type that is defined in a

83

DEFINE ORDINAL, or DEFINE STRUCTURE statement or in another DEFINE ALIAS statement. Also, as in the RETURNS option and attribute,
any string lengths or area sizes must be restricted expressions.

5

Missing data attributes are supplied using PL/I defaults.
Public Attributes:
attribute : String

10

PLIOrdinal

An ordinal is a named set of ordered values. Using the DEFINE ORDINAL statement, you can define an ordinal and assign meaningful names to be used to refer to that set. For example, you can define an ordinal called "color". The "color" ordinal could include the members "red", "yellow", "blue", etc. The members of the "color" set can then be referred to by these names instead of by their associated fixed binary value, making code much more self-documenting. Furthermore, a variable declared with the ordinal type can be assigned and compared only with an ordinal of the same type, or with a member of that ordinal type. This automatic checking provides for better program reliability.

15

20

In the following example, Red has the value 0, Orange has the value 1, etc. But Low has the value 2 and Medium has the value 3.

25

Example

```
define ordinal Color ( Red,        /* is 0, since VALUE is omitted */
                       Orange,
                       Yellow,
                       Green,
                       Blue,
                       Indigo,
                       Violet );

define ordinal Intensity ( Low    value(2),
                           Medium,
                           High   value(5));
```

35

40

Public Attributes:
precision : int
isSigned : boolean

5

OrdinalValue
OrdinalValue specifies the value of a particular member within the set. If the VALUE attribute is omitted for the first member,
a value of zero is used. If the VALUE attribute is omitted for any other member, the next greater integer value is used.

10

The value in the given (or assumed) VALUE attribute must be an integer, can be signed, and must be strictly increasing. The value in
the given (or assumed) VALUE attributed may also be specified as an XN constant.

15

Example
define ordinal Intesity (low vcalue(2), middle, high value (5));

20

will giive low a value of 2, middle a value of 3, and high a value of 5.
Public Attributes:
name : String
value : int

25

PLIStructure
A structure is a collection of member elements that can be structure, unions, or elementary variables and arrays.

30

Unions are a collection of member elements that overlay each other, occupying the same storage. Unions
can be used to declare variant records that typically contain a common part, a selector part, and a variant part

35

DEFINE STRUCTURE statement is used to specify a named structure or union. Structures are stronly typed. That is only variables declared as structures can be assigned to variables or parameters declared as structures.

40

Derived from PLINamedType, PLIComposedType

PLIHandleType
> use HANDLE to declare a variable as a pointer to a structure type.
> Handle are strongly typed - they can be assigned to or compared with
> handles for the same structure type

10

PLINamedType
> PL/I allows you to define your own named types using the built-in data
> types. These include user-defined types (aliases,ordinals, structures, and
> unions), declarations of variables with these types, handles, and type
> functions.
> Derived from PLIClassifier

15

PLIArray
> An array is an n-dimensional collection of elements that have idenical
> attributes.

20

> Examples

> dcl List fixed decimal(3) dimension(8)

> is a 1 dimensional array with 8 fixed-point decimal elements

25

> dcl table (4,2) fixed dec (3)

> is a 2 dimensional array of three fixed -point decimal elements the 2
> dimensions of table have lower bounds of 1 and upper bounds of 4 for 1
> dimension
> and lower bounds of 1 and upper bounds of 2 for the other

30

> The REFER option is used in the declaration of a based structure to
> specify that, on allocation of the structure, the value of an expression is
> assigned to a variable in the structure and represents the length, bound, or
> size of another variable in the structure. The syntax for a length, bound, or
> size with a REFER option is:

35

40

> expression REFER (variable)

> The variable, known as the object of the REFER option, must be a
> member of the declared structure. The REFER object must conform to the
> following rules:

45

86

It must be REAL FIXED BINARY(p,0).

It must precede the first level-2 element that has the REFER option or contains an element that has the REFER option.

It must not be locator-qualified or subscripted.

It must not be part of an array.

For example:

```
DECLARE 1 STR BASED(P),
    2 X FIXED BINARY,
    2 Y (L REFER (X)),
    L FIXED BINARY INIT(1000);
```

This declaration specifies that the based structure STR consists of an array Y and an element X. When STR is allocated, the upper bound is set to the current value of L which is assigned to X. For any other reference to Y, such as a READ statement that sets P, the bound value is taken from X.

If both the REFER option and the INITIAL attribute are used for the same member, initialization occurs after the object of the REFER has been assigned its value.

Any number of REFER options can be used in the declaration of a structure, provided that at least one of the following restrictions is satisfied:

All objects of REFER options are declared at logical level two, that is, not declared within a minor structure. For example:

```
DECLARE 1 STR BASED,
    2 (M,N),
    2 ARR(I REFER (M),
     J REFER(N)),
    2 X;
```

When this structure is allocated, the values assigned to I and J set the bounds of the two-dimensional array ARR.

The structure is declared so that no padding between members of the structure can occur. For example:

87

```
DECLARE 1 STR UNAL BASED (P),
     2 B FIXED BINARY,
     2 C,
       3 D FLOAT DECIMAL,
       3 E (I REFER (D))
         CHAR(J REFER (B)),
     2 G FIXED DECIMAL;
```

All items require only byte alignment because this structure has the UNALIGNED attribute. Therefore, regardless of the values of B and D (the REFER objects) no padding occurs. Note that D is declared within a minor structure.

If the REFER option is used only once in a structure declaration, the two preceding restrictions can be ignored provided that:

For a string length or area size, the option is applied to the last element of the structure.

For an array bound, the option is applied either to the last element of the structure or to a minor structure that contains the last element. The array bound must be the upper bound of the leading dimension. For example:

```
DCL 1 STR BASED (P),
     2 X FIXED BINARY,
     2 Y,
       3 Z FLOAT DECIMAL,
       3 M FIXED DECIMAL,
     2 D (L REFER (M)),
       3 E (50),
       3 F (20);
```

The leading dimension of an array can be inherited from a higher level. If we had declared STR(4) in the above example, the leading dimension would be inherited from STR(4) and so it would not be possible to use the REFER option in D.

This declaration does not satisfy the two previous bulleted restrictions. The REFER object M is declared within a minor structure and padding occurs. However, this restriction is satisfied because the REFER option is applied to a minor structure that contains the last element.

The following example is also valid:

```
DCL 1 STR BASED(P),
    2 X FIXED BINARY(31),
    2 Y,
        3 Z FLOAT DECIMAL,
        3 M FIXED BINARY(31),
        3 N FIXED BINARY(31),
    2 D,
        3 E(50),
        3 F(L REFER (M))
            CHAR(K REFER (N));
```

If the value of the object of a REFER option varies during the program then:

The structure must not be freed until the object is restored to the value it had when allocated.

The structure must not be written out while the object has a value greater than the value it was allocated.

The structure can be written out when the object has a value equal to or less than the value it had when allocated. The number of elements, the string length, or area size actually written is that indicated by the current value of the object. For example:

```
DCL 1 REC BASED (P),
    2 N,
    2 A (M REFER(N)),
    M INITIAL (100);
ALLOCATE REC;
N = 86;
WRITE FILE (X) FROM (REC);
```

86 elements of REC are written. It would be an error to attempt to free REC at this point, since N must be restored to the value it had when allocated (that is, 100). If N is assigned a value greater than 100, an error occurs when the WRITE statement is encountered.

When the value of a refer object is changed, the next reference to the structure causes remapping. For example:

```
DCL 1 A BASED(P),
```

89

```
        2 B,
        2 C (I REFER(B)),
        2 D,
    I INIT(10);
```

5

```
    ALLOCATE A;
    B = 5;
```

10   The next reference to A after the assignment to B remaps the structure to reduce the upper bound of C from 10 to 5, and to allocate to D storage immediately following the new last element of C. Although the structure is remapped, no data is reassigned--the contents of the part of storage originally occupied by the structure A are unchanged. If you do not
15   consider remapping, errors can occur. Consider the following example, in which there are two REFER options in the one structure:

```
    DCL 1 A BASED (P),
        2 B FIXED BINARY (15,0),
20      2 C CHAR (I1 REFER (B)),
        2 D FIXED BINARY (15,0),
        2 E CHAR (I2 REFER (D)),
    (I1,I2) INIT (10);
```

25
```
    ALLOCATE A;
    B = 5;
```

30   The mapping of A with B=10 and B=5, respectively, is as follows:

```
    | B |   C   | D |    E     |
    |__ |_____|___|_____|
```

35
```
    | B |  C  | D |   E
    |__ |_____|___|_ _ _ _ _ _ _
```

40   D now refers to data that was originally part of that assigned to the character-string variable C. This data is interpreted according to the attributes of D--that is, as a fixed-point binary number--and the value obtained is the length of E. Hence, the length of E is unpredictable.

return for the DirectionKind, and the enumeration of true and false for the Boolean

datatype in the C Language Metamodel.

5.   c.   i.   C Metamodel Specification

5   The C metamodel is used by enterprise application programs to define data structures

which represent connector interfaces.

Classifier

10   Type specifiers indicate the type of the object or function you are

declaring. The fundamental data types are:

Characters

Floating-Point Numbers

15   Integers

Enumerations

Void

From these types, you can derive:

20

Pointers

Arrays

Structures

Unions

25   Functions

The integral types are char, wchar_t(C++ only), and int of all sizes.

Floating-point numbers can have types float, double, or long double. You

can collectively refer to integral and floating-point types as arithmetic

30   types. In C++ only, you can also derive the following:

STL920000075US2

References

Classes

Pointers to Members

5   In C++, enumerations are not an integral type, but they can be subject to integral promotionThis is the base class that defines types in CMain.

It provides a classification of instances through a set of Features it contains.

10

Classifiers are defined largely by a composition of Features.

Derived from TDLangClassifier

15

Public Attributes:

name : String

Structured

20   This is the abstract class for structured types.

Derived from Classifier, TDLangComposedType, DerivableType, StructureContents

25   Struct

A structure contains an ordered group of data objects. Unlike the elements of an array, the data objects within a structure can have varied data types. Each data object in a structure is a member or field.

30

94

Use structures to group logically related objects. For example, to allocate storage for the components of one address, define the following variables:

5

```
int street_no;
char *street_name;
char *city;
char *prov;
char *postal_code;
```

10

To allocate storage for more than one address, group the components of each address by defining a structure data type and as many variables as you need to have the structure data type.

15 In the following example, lines 1 through 7 declare the structure tag address:

```
1   struct address {
2           int street_no;
3           char *street_name;
4           char *city;
5           char *prov;
6           char *postal_code;
7           };
8   struct address perm_address;
9   struct address temp_address;
10  struct address *p_perm_address = &perm_address;
```

20

25

The variables perm_address and temp_address are instances of the
30 structure data type address. Both contain the

members described in the declaration of address. The pointer

p_perm_address points to a structure of address and is

initialized to point to perm_address.

5   Refer to a member of a structure by specifying the structure variable

name with the dot operator (.) or a pointer with the

arrow operator (->) and the member name. For example, both of the

following assign a pointer to the string "Ontario" to

the pointer prov that is in the structure perm_address:

10

perm_address.prov = "Ontario";

p_perm_address -> prov = "Ontario";

All references to structures must be fully qualified. In the example, you

15   cannot reference the fourth field by prov alone. You

must reference this field by perm_address.prov.

Structures with identical members but different names are not compatible

and cannot be assigned to each other. Structures

20   are not intended to conserve storage. If you need direct control of byte

mapping, use pointers.

Derived from Structured

Union

25   A union is an object that can hold any one of a set of named members.

The members of the named set can be of any data

type. C/C++ overlays the members in storage.

The storage allocated for a union is the storage required for the largest

30   member of the union (plus any padding that is required

so that the union will end at a natural boundary of its strictest member).

.

96

C++ Notes:

1. In C++, a union can have member functions, including constructors
and destructors, but not virtual member

functions. You cannot use a union as a base class nor derive it from a base

class.

2. A C++ union member cannot be a class object that has a

constructor, destructor, or overloaded copy assignment

operator. In C++, you cannot declare a member of a union with the

keyword static.

Derived from Structured

BehavioralFeature

This defines a dynamic characteristic of the ModelElement that contains

it. A BehavioralFeature is both a Feature and a Namespace.

Public Attributes:

name : String

TypedElement

This is the base class for attribute, parameter and constant whose

definition requires a type specification. The TypeElement type is an

abstraction of ModelElements that require a type as part of their definition.

A TypeElement does not itself define a type, but is associated with a

Classifier.

Derived from TDLangElement

StructuralFeature

It defines a static characteristic of the ModelElement that contains it.

1

Derived from TypedElement, StructureContents

97

Public Attributes:

name : String

5   l Parameter

A Parameter provides a means of communication with operations and

other BehavioralFeatures. A parameter passes or communicates values of

its defined type.

10   A function declarator contains an identifier that names a function, and a

contains a list of the function parameters. You

should always use prototype function declarators because you can check

the function parameters with them. C++ functions

must have prototype function declarators.

15

Prototype Function Declarators: You should declare each parameter

within the function declarator. Any calls to the

function must pass the same number of arguments as there are parameters

in the declaration.

20

Nonprototype Function Declarators: You should declare each parameter

in a parameter declaration list following the

declarator. If you do not declare a parameter, it has type int.

25   The compiler widens char and short parameters to int, and widens float

parameters to double. The compiler performs

no type checking between the argument type and the parameter type for

nonprototyped functions. As well, it does not check

to ensure that the number of arguments matches the number of

30   parameters.

You should declare each value that a function receives in a parameter declaration list for nonprototype function definitions that follows the declarator.

5 A parameter declaration determines the storage class specifier and the data type of the value.

The only storage class specifier that C/C++ allows is the register storage class specifier. It allows any type

10 specifier for a parameter. If you do not specify the register storage class specifier, the parameter will have the auto storage class specifier. In C only, if you omit the type specifier and you are not using the prototype form to define the function, the parameter will have type int, as follows:

15

```
int func(i,j)
{
  /*  i and j have type int  */
}
```

20

In C only, you cannot declare a parameter in the parameter declaration list if it is not listed within the declarator.

Array

10   An array is an ordered group of data objects. Refer to each object as an
element. All elements within an array have the same data type.

Use any type specifier in an array definition or declaration. Array
elements can be of any data type, except function or, in
15   C++, a reference. You can, however, declare an array of pointers to
functions.
Derived from Derived

Public Attributes:
20   dimension : Integer

Pointer

A pointer type variable holds the address of a data object or a function. A
25   pointer can refer to an object of any one data type
except to a bit field or a reference. Additionally, in C, a pointer cannot
point to an object with the register storage class.

Some common uses for pointers are:

30

To access dynamic data structures such as linked lists, trees, and queues.

To access elements of an array, or members of a structure, or members

5   of a C++ class.

To access an array of characters as a string.

To pass the address of a variable to a function. (In C++, you can also

10   use a reference to do this.) By referencing a

variable through its address, a function can change the contents of that

variable.

5.   d.   C++ Metamodel

25

The C++ metamodel, based on the ANNOTATED C++ REFERENCE MANUAL book
(authors: Margaret A. Ellis, Bjarne Stoustrup), 1990, is a MOF Class instance at the M2
level. The C++ metamodel consists of C++ Main, and Model Types described as follows:

30   **5.   d.   i.   C++ Main Metamodel:**

STL920000075US2

This metamodel inherits from the C Main metamodel. FIGURE 24 illustrates the C++ Main Metamodel, including Derived, Structured, BehavioralFeatures, Field, and DerivableTypes for the C++ Metamodel. FIGURE 25 illustrates an enumeration of the visibility types for the C++ Metamodel. Note that C++ is an object oriented language,

5 useful in object oriented programming, and supports public, private, and protected visibilities.

Model Types Metamodel:

10 **5.   d.   ii.   C++ Metamodel Specificiation**

C++

The C metamodel is used by enterprise application programs to define data structures which represent connector interfaces.

Class

15 The C++ class is an extension of the C-language structure. The only difference between a structure and a class is that

structure members have public access by default and class members have private access by default. Consequently, you can

use the keywords class or struct to define equivalent classes.

20

// In this example, class X is equivalent to struct Y

```
class X
{
int a; // private by default
public:
    int f() { return a = 5; }; // public member function
};
struct Y
{
int f() { return a = 5; };      // public by default
```

25

30

```
    private:

        int a; // private data member

    };
```

5   If you define a structure and then declare an object of that structure using the keyword

class, the members of the object are

still public by default. In the following example, main() has access to the members of X

even though X is declared as using

the keyword class:

10   Derived from Structured

Public Attributes:

isAbstract : Boolean

15

Private Attributes:

visibility : VisibilityKind

Member

20   Data members include members that are declared with any of the fundamental types, as

well as other types, including pointer,

reference, array types, and user-defined types. You can declare a data member the same

way as a variable. However, you

cannot place explicit initializers inside the class definition.

25

If you declare an array as a nonstatic class member, you must specify all the array

dimensions.

Template

The declaration in a template declaration must define or declare one of the following:

20   A class

A function

A static member of a template class

The identifier of a type is a type_name in the scope of the template declaration. A

25   template declaration can appear as a

global declaration only.

The template arguments (within the < and > delimiters) specify the types and the

constants within the template that you must

30   specify when the template is instantiated.

Given the following template:

```
template<class L> class Key
    {
      L k;
      L* kptr;
      int length;
  public:
      Key(L);
      // ..;
  // ...
    };
```

The declarations create the following objects:

i of type Key<int>

c of type Key<char*>

m of type Key<mytype>

Note that these three classes have different names. The types that are contained within the angle braces are not arguments to the class names, but part of the class names themselves. Key<int> and Key<char*> are class names. Within the context of the example, a class that is called Key (with no template argument list) is undefined.

C++ permits default initializers in template arguments under the following conditions:

They only apply to nontype template arguments.

They only apply to trailing arguments, like functions.

Subsequent template declarations can add default initializers, but cannot redefine existing default initializers.

They only apply to class template declarations, not to function template declarations.

STL920000075US2

Note: C++ treats a template that defines a member function of a class template as a function template. Such a template cannot have default initializers.

HLASMDecimal
20   HLASMDecimal types are used by decimal instructions
            Code is 'P' for decimal type (machine format: packed decimal format).
            Code is 'Z' for decimal type (machine format: zoned decimal format).

            Examples:
25   AP   AREA,PCON
            PCON   DC   P'100'
            AREA   DS   P
            Derived from HLASMSimpleType

30   Private Attributes:
            exponent : int
                 The exponent modifier specifies the power of 10 by which the nominal value of a decimal constant is to be multiplied before it is converted to its internal binary representation.
35   **packed : boolean**
                 This boolean corresponds to the machine format for decimal type.

108

True is Packed (Code is P)

False is Zoned (Code is Z)

scale : int

The scale modifier specifies the amount of internal scaling you want for decimal constants.

HLASMAddress

HLASMAddress holds address information mainly for the use of fixed-point and other instructions   Code is 'A' for address type (machine format: value of address; normally a fullword).

Code is 'AD' for address type (machine format: value of address; normally a doubleword).

Code is 'Y' for address type (machine format: value of address; normally a halfword).

Code is 'S' for address type (machine format: base register and displacement value; a halfword).

Code is 'V' for address type (machine format: space reserved for external symbol address; normally a fullword).

Code is 'J' for address type (machine format: space reserved for length of class or DXD; normally a fullword).

Code is 'Q' for address type (machine format: space reserved for external dummy section offset).

Code is 'R' for address type (machine format: space reserved for PSECT addresses; normally a fullword).

Example:
```
        L       5,ADCON
ADCON  DC       A(SOMWHERE)
```
Derived from HLASMSimpleType

Private Attributes:

type : HLASMAddressType

Specifies this element's address type.

HLASMBinary

HLASMBinary defines bit patterns.

Code is 'B' for binary type (machine format: binary format).

Example:
```
FLAG       DC B'00010000'
```
Derived from HLASMSimpleType

109

Private Attributes:

exponent : int

The exponent modifier specifies the power of 10 by which the nominal value of a binary constant is to be multiplied before it is converted to its internal binary representation.

scale : int

The scale modifier specifies the amount of internal scaling you want for binary constants.

HLASMCharacter

HLASMCharacter defines character strings or messages.

Code is 'C' for character type (machine format: 8-bit for each character).

Code is 'CU' for unicode character type (machine format: 16-bit code for each character).

Code is G' for graphic type (machine format: 16-bit code for each character)

Example:

CHAR   DC   C'string of characters'

Derived from HLASMSimpleType

Private Attributes:

graphic : boolean

Specifies whether the element is graphic or not.

True for Graphic (Code is 'G').

False for regular character type.

type : HLASMCharacterType

Specifies this element's character type.

HLASMFixedPoint

HLASMFixedPoint types are used by the fixed-point and other instructions.

Code is 'F' for fixed-point type (machine format: signed, fixed-point binary format; normally a fullword).

Code is 'FD' for fixed-point type (machine format: signed, fixed-point binary format; normally a doubleword).

Code is 'H' for fixed-point type (machine format: signed, fixed-point binary format; normally a halfword).

Example:

L   3,FCON

110

FCON   DC   F'100'
Derived from HLASMSimpleType

Private Attributes:

exponent : int

The exponent modifier specifies the power of 10 by which the nominal value of a fixed-point constant (H, F) is to be multiplied before it is converted to its internal binary representation.

The exponent modifier is written as En, where n can be either a decimal self-defining term, or an absolute expression enclosed in parentheses.

The decimal self-defining term or the expression can be preceded by a sign: If no sign is present, a plus sign is assumed. The range for the exponent modifier is -85 to +75. If using the type extension to define a floating-point constant, the exponent modifier can be in the range -2(31) to 2(31)-1. If the nominal value cannot be represented exactly, a warning message is issued.

scale : int

The scale modifier specifies the amount of internal scaling you want for binary digits for fixed-point constants (H, F), i.e. the power of two by which the fixed-point constant must be multiplied after its nominal value has been converted to its binary representation, but before it is assembled in its final scaled form. Scaling causes the binary point to move from its assumed fixed position at the right of the extreme right bit position.

The range for each type of constant is:

Fixed-point constant H
-187 to 15
Fixed-point constant F
-187 to 30

The scale modifier is written as Sn, where n is either a decimal self-defining term, or an absolute expression enclosed in parentheses.
I Both forms of the modifier's value n can be preceded by a sign; if no sign is present, a plus sign is assumed.

Notes:

1. When the scale modifier has a positive value, it indicates the number of binary positions occupied by the fractional portion of the binary number.

2. When the scale modifier has a negative value, it indicates the number of binary positions deleted from the integer portion of the binary number.

STL920000075US2

3. When low-order positions are lost because of scaling (or lack of scaling), rounding occurs in the extreme left bit of the lost portion. The rounding is reflected in the extreme right position saved.

5

HLASMFloatingPoint

10

HLASMFloatingPoint types are used by floating-point instructions.
Code is 'E' for floating-point type (machine format: short floating-point format; normally a fullword).
Code is 'D' for floating-point type (machine format: long floating-point format; normally a doubleword).

15

Code is 'L' for floating-point type (machine format: extended floating-point format; normally doublewords).

Examples:

20

```
          LE   2,ECON
ECON      DC   E'100.50'
```
Derived from HLASMSimpleType

Private Attributes:

25

exponent : int

The exponent modifier specifies the power of 10 by which the nominal value of a floating-point constant (E, D, and L) is to be multiplied before it is converted to its internal binary representation.

30

The exponent modifier is written as En, where n can be either a decimal self-defining term, or an absolute expression enclosed in parentheses.

The decimal self-defining term or the expression can be preceded by a sign: If no sign is present, a plus sign is assumed. The range for the

35

exponent modifier is -85 to +75. If using the type extension to define a floating-point constant, the exponent modifier can be in the range $-2(31)$ to $2(31)-1$. If the nominal value cannot be represented exactly, a warning message is issued.

round : HLASMFloatingPointRoundType

40

Specifies this element's floating point round type.

scale : int

The scale modifier specifies the amount of internal scaling you want for hexadecimal digits for floating-point constants (E, D, L), i.e. the power of two by which the fixed-point constant must be multiplied after its nominal

45

value has been converted to its binary representation, but before it is assembled in its final scaled form. Scaling causes the binary point to move

112

from its assumed fixed position at the right of the extreme right bit position.

The range for each type of constant is:

Floating-point constant E
0 to 5
Floating-point constant D
0 to 13
Floating-point constant L
0 to 27

The scale modifier is written as Sn, where n is either a decimal self-defining term, or an absolute expression enclosed in parentheses.
I Both forms of the modifier's value n can be preceded by a sign; if no sign is present, a plus sign is assumed.

Scale Modifier for Hexadecimal Floating-Point Constants: The scale modifier for hexadecimal floating-point constants must have a positive value. It specifies the number of hexadecimal positions that the fractional portion of the binary representation of a floating-point constant is shifted to the right. The hexadecimal point is assumed to be fixed at the left of the extreme left position in the fractional field. When scaling is specified, it causes an unnormalized hexadecimal fraction to be assembled (unnormalized means the leftmost positions of the fraction contain hexadecimal zeros). The magnitude of the constant is retained, because the exponent in the characteristic portion of the constant is adjusted upward accordingly. When non-zero hexadecimal positions are lost, rounding occurs in the extreme left hexadecimal position of the lost portion. The rounding is reflected in the extreme right position saved.

type : HLASMFloatingPointType
Specifies this element's floating point type.

HLASMHexadecimal
HLASMHexadecimal defines large bit patterns.
Code is 'X' for hexadecimal type (machine format: 4-bit code for each hexadecimal digit).

Example:
PATTERN   DC   X'FF00FF00'
Derived from HLASMSimpleType

HLASMClassifier
> HLASMClassifier is the abstract parent class of HLASMComposedType and HLASMSimpleType.
> Derived from TDLangClassifier

5

HLASMElement
> A HLASMElement represents every DC instruction in the HLASM program.

10
> For example:
> CHAR   DC   C'string of characters'
> PCON   DC   P'100'
> PATTERN DC   X'FF00FF00'
> CHAR, PCON, and PATTERN are all DC instructions

15
> Derived from TDLangElement

HLASMSimpleType
> HLASMSimpleType is an abstract class that contains attributes shared by all simple types in the HLASM language.

20
> Derived from HLASMClassifier

> Private Attributes:
> **length : int**
25
> The length modifier indicates the number of bytes of storage into which the constant is to be assembled. It is written as Ln, where n is either a decimal self-defining term or an absolute expression enclosed by parentheses. It must have a positive value.

30
> When the length modifier is specified:

> Its value determines the number of bytes of storage allocated to a constant. It therefore determines whether the nominal value of a constant must be padded or truncated to fit into the space allocated.

35
> No boundary alignment, according to constant type, is provided.

> Its value must not exceed the maximum length allowed for the various types of constant defined.

40
> The length modifier must not truncate double-byte data in a C-type constant.

> I The length modifier must be a multiple of 2 in a G-type or CU-type
45
> I constant.

114

When no length is specified, for character and graphic constants (C and G), hexadecimal constants (X), binary constants (B), and decimal constants (P and Z), the whole constant is assembled into its implicit length.

size : HLASMSizeType
Specifies this element's boundary alignment.

HLASMComposedType
The HLASMComposedType class represents a nested declaration that contains additional elements. HLASMComposedType class is an aggregate of HLASMElements. HLASMComposedType is parent of HLASMUnion.

Derived from HLASMClassifier, TDLangComposedType

Private Attributes:
union : boolean
Specifies whether the element is a union or not.

True for union.
False otherwise.

HLASMArray
HLASMArray holds information for array instructions.
Private Attributes:
size : int
Size denotes the one-dimensional size of the array that is allocated in memory.

HLASMElementInitialValue
This class contains the initial value of the HLASMelement.
Derived from TDLangElement
Public Attributes:
initVal : String
Specifies the initial value of the element, example: 'MIN', 'MAX', etc.

STL920000075US2

HLASMSourceText
> This class contains the entire source code (including comments) and its associated line number.

Public Attributes:

source : String
> Specify the source file string.

fileName : String
> Specifies the path of the source file.

6. Application-Domain Interface Metamodel

6. a. IMS Transaction Message Metamodel

The IMS Transaction Message metamodel depicted as shownj in FIGURE 26 (FIGURE 26 illustrates the Metamodel for an IMS Transaction Message, containing three types of transaction messages, the IMS-OTA Messages with a prefix, IMS messages without a prefix where a default OTMA prefix can be built by IMS, and IMS basic messages to be sent to application programs, directly), containing three types of IMS transaction messages:

* IMS OTMA messages with prefix

* IMS messages without prefix - A default OTMA prefix can be built by IMS

* IMS basic messages to be sent to application programs directly

6. a. i. IMS OTMA Prefix

An IMS OTMA message prefix is composed of the following components, FIGURE 27 illustrates the OTMA prefix metadata model. FIGURE 28 illustrates the OTMA prefix in control data defined data types. FIGURE 29 illustrates the OTMA prefix in state defined data types. FIGURE 30 illustrates the OTMA prefix in security defined types. FIGURE 31 illustrates the IMS Messages primitives in the IMS Metamodel.

* Control data: This section includes the transaction-pipe name, message type, sequence numbers, flags and indicators.

* State data: This section includes a destination override, map name, synchronization level, commit mode, tokens and server state.

* Security data: This section includes the user ID, user token, and security flags.

* User data: This section includes any special information needed by the client.

The OTMA prefix metamodel is characterized as follows.

1) OTMA Prefix - Control Data Defined Types

2) OTMA Prefix - State Data Defined Types

3) OTMA Prefix - Security Data Defined Types

6.   a.   ii.   IMS Messages Primitive Types

6.   a.   i.   a).   IMSTransactionMessage Metamodel Specification

IMSTransactionMessage metamodel includes the following IMS messages scenarios:

- IMS OTMA messages with the prefix

- IMS OTMA messages without the prefix

- IMS basic messages to be sent to the application program directly.

Private Attributes:

OTMAPrefixFormat : OTMAPrefixFormats = one

StandardFieldsFlag : boolean

117

OTMAPrefixFormats

Private Attributes:

one :

5   two :

StandardFields

StandardFields (consisting LL, ZZ and transaction code) are not included

in the following scenarios:

10   - Sending XML documents directly to the IMS transaction application

programs

- ACK or NAK messages to IMS applications

Private Attributes:

Length : TwoByteField

15   Also known as LL.

ReservedField : TwoByteField

Also known as ZZ.

TransactionCode : VariableLengthField

The Transaction Code field can be from 1 to 8 bytes in length.

20   TransactionCode appears with first segment of input messages only.

TransactionCode comes after LLZZ.

OTMAPrefix

25   OTMAPrefix

An IMS OTMA prefix can appear either before all message segments, or

only before the first segment of the message. However, the OTMA prefix

is optional. If it is not specified, the IMS gateway will build a default one

for the request.

30

ControlData.

Control data is message-control information. It includes the transaction-pipe name, message type, sequence numbers, flags and indicators.

Private Attributes:

ArchitectureLevel : OneByteField

Specifies the OTMA architecture level. The client specifies an architecture level, and the server indicates in the response message which architecture level it is using. The architecture levels used by a client and a server must match.

With IMS Version 6, the only valid value is X'01'.

Mandatory for all messages.

MessageType : TMessageType

Specifies the message type. Every OTMA message must specify a value for the message type. The values are not mutually exclusive. For example, when the server sends an ACK message to a client-submitted transaction, both the transaction and response flags are set.

ResponseFlag : OneByteField

Specifies either that the message is a response message or that a response is requested.

Acknowledgements to transactions include attributes (for that transaction) in the application-data section of the message prefix only if the transaction specifies Extended Response Requested.

CommitConfirmationFlag : TCommitConfirmationFlag

Specifies the success of a commit request. Sent by the server to the client in a commit-confirmation message. These messages are only applicable for send-then-commit transactions, and are not affected by the synchronization-level flag in the state-data section of the message prefix.

CommandType : TCommandType

Specifies the OTMA protocol command type.

IMS MTO commands are specified in the application-data section of the mesage.

ProcessingFlag : TProcessingFlag

119

Specifies options by which a client or aserver can control message processing.

TpipeName : EightByteField

Specifies the transaction-pipe name. For IMS, this name is used to override the LTERM name on the I/O PCB. This field is applicable for all transaction, data, and commit-confirmation message types. It is also applicable for certain response and command message types.

ChainFlag : TChainFlag

Specifies how many segments are in the message. This flag is applicable to transaction and data message types, and it is mandatory for multi-segment messages.

PrefixFlag : TPrefixFlag

Specifies the sections of the message prefix that are attached to the OTMA message. Every message must have the message-control information section, but any combination of other sections can be sent with an OTMA message.

SendSequenceNumber : FourByteField

Specifies the sequence number for a transaction pipe. This sequence number is updated by the client and server when sending message or transactions.

Recommendation: Increment the number separately for each transaction pipe.

This number can also be used to match an ACK or NAK message with the specific message being acknowledged.

SenseCode : TwoByteField

Specifies the sense code that accompanies a NAK message.

ReasonCode : TwoByteField

Specifies the reason code that accompanies a NAK message. This code can further qualify a sense code.

RecoverableSequenceNumber : FourByteField

120

Specifies the recoverable sequence number for a transaction pipe. Incremented on every send orf a recoverable message using a synchronized transaction pipe. Both the client and the server increment their recoverable send-sequence numbers and maintain them separately

5 from the send-sequence number.

SegmentSequenceNumber : TwoByteField

Specifies the sequence number for a segment of a multi-segment message. This number must be updated for each segment, because messages are not

10 necessarily delivered sequentially by XCF.

This number must have a value of 0 (zero) if the message has only one segment.

Reserved : TwoByteField

15 DefinedTypes

TMessageType

Private Attributes:

Data : String

20 Data (value X'80')

Specifies server output data sent to the client. If the client specifies synchronization level Confirm in the state-data section of the message prefix, the server also sets Response Requested for the response flag. If the client does not specify a synchronization level, the server uses the

25 default, Confirm.

Transaction : String

Transaction (value X'40')

Specifies client input data to the server.

Response : String

30 Response (value X'20')

Specifies that the message is a response message, and is only set if the

message for which this message is the response specified Response

Requested for the response flag.

If this flag is set, the response flag specifies either ACK or NAK.

5   The send-sequence numbers must match for the original data message and

the response message. Chained transaction input messages to the server

must always request a response before the next transaction (for a particular

transaction pipe) is sent.

Command : String

10   Command (value X'10')- Specifies an OTMA protocol command. OTMA

commands must always specify Response Requested for the Response

flag.   -

CommitConfirmation : String

CommitConfirmation (value X'08') - Specifies that commit is complete.

15   This is sent by the server when a sync point has completed, and is only

applicable for send-then-commit transactions. The commit-confirmation

flag is also set.

TResponseFlag

20   Private Attributes:

ACK : String

ACK (value X'80') Specifies a positive acknowledgement.

NAK : String

NAK (value X'40') Specifies a negative acknowledgement.

25   See the sense code field for more information on the reason for the NAK.

ResponseRequested : String

Response Requested (value X'20') Specifies that a response is requested

for this message. This can be set for message types of Data, Transaction,

or Command.

30   When sending send-then-commit IMS command output, IMS does not

request an ACK regardless of the synchronization level.

122

ExtendedResponseRequested : String

Extended Response Requested (value X'10') - Specifies that an extended response is requested for this message. Can be set by a client only for transactions (or for transactions that specify an IMS command instead of a transaction code). If this flag is set for a transaction, IMS returns the architected attributes for that transaction in the application-data section of the ACK message. If this flag is set for a command, IMS returns the architected attributes in the application-data section of the ACK message. This flag can be set for the IMS commands /DISPLAY TRANSACTION and /DISPLAY TRANSACTION ALL.

TCommitConfirmationFlag

    Private Attributes:

    Committed : String

    Committed (value X'80') - Specifies that the server committed successfully.

    Aborted : String

    Aborted (value X'40') - Specifies that the server aborted the commit.

TCommandType

    Private Attributes:

    ClientBid : String

    Client-Bid (value X'04')- Specifies the first message a client sends to the OTMA server. This command must also set the response-requested flag and the security flag in the message-control information section of the message prefix. The appropriate stat-data fields (for example, Member Name) must also be set. The security-data prefix must specify a Utoken field so the OTMA server can validate the client's authority to act as an OTMA client. Because the server can respond to the client-bid request, this message should nto be sent until the client is ready to start accepting data messages.

123

ServerAvailable : String

Server Available (value X'08') - Specifies the first message the server sends to a client. It is sent when the server has connected to the XCF group before the client has connected. The client replies to the server

5   Available message with a client-bid request. The appropriate state data fields (for example, Member Name) must also be set. If the client connects first, it is notified by XCF when the server connects, and begins processing with a client-bid request.

CBresynch : String

10   CBresynch (value X'0C') - Specifies a client-bid message with a request by the client for resynchronization. This command is optional and causes the server to send an SRVresynch message to the client. The CBresynch command is the first messag ethat a client sends to the OTMA server when it attempts to resynchronize with IMS and existing synchronized

15   Tpipes exist for the client. Other than the CBresynch message indicator in the message prefix, the information required for the message prefix should be identical to the client-bid command. If IMS receives a client-bid request for them client and IMS is aware of existing synchronized Tpipes, IMS issues informational message DFS2394I to the MTO. IMS resets the

20   recoverable send- or receive- sequence numbers to 0 (zero) for all the synchronized Tpipes.

SuspendProcessingForAllTpipes : String

Suspend Processing for All Tpipes (value X'14') - Specifies that the server is suspending all message activity with the client. All subsequent data

25   input receives a NAK message from the server. Similarly, the client should send a NAK message for any subsequent server messages. If a client wishes to suspend processing for a particular transaction pipe, it must submit a /STOP TPIPE command as an OTMA message.

ResumeProcessingForAllTpipes : String

30   Resume processing for All Tpipes (value X'18') - Specifies that the server is resuming message activity with the client. If a client wishes to resume

124

processing for a particular transaction pipe that has been stopped, it must submit a /START TPIPE command as an OTMA message.

SuspendInputForTpipe : String

Suspend Input for Tpipe (value X'1C') - Specifies that the server is overloaded and is temporarily suspending input for the transaction pipe. All subsequent client input receive NAK messages for the transation pipe specified in the message-control information section of the message prefix. A response is not requested for this command. This architected command is also sent by IMS when the master terminal operator enters a /STOP TPIPE command.

ResumeInputForTpipe : String

Resume Input for Tpipe (value X'20') Specifies that the server is ready to resume client input following an earlier Suspend Input for Tpipe command. A response is not requested for this command. This command is also sent by IMS when the IMS master terminal operator issues a /START TPIPE command.

SRVresynch : String

SRVresynch (value X'2C') - Specifies the server's response to a client's CBresynch command. This command specifies the states of synchronized transaction pipes within the server (the send- and receive-sequence numbers). This command is sent as a single message (with single or multiple segments), and an ACK is requested.

REQresynch : String

REQresynch (value X'30') - Specifies the send-sequence number and the receive sequence for a particular Tpipe. REQresynch is send from IMS to a client.

REPresynch : String

REPresynch (value X'34') - Specifies the client's desired state information for a Tpipe. A client sends the REPresynch comand to IMS in response to the REQresynch command received from IMS.

TBresynch : String

125

TBresynch (value X'38') - Specifies that the client is ready to receive the REQresynch command from IMS.

TProcessingFlag

Private Attributes:

SynchronizedTpipe : String

Synchronized Tpipe (value X'40') - Specifies that the transaction pipe is to be synchronized. Allows the client to resynchronize a transaction pipe if there is a failure. Only valid for commit-then-send transactions. This flag causes input and output sequence numbers to be maintained for the transaction pipe. All transactions routed through the transaction pipe must specify this flag consistently (either on or off).

1 AsynchronousOutput : String

Asynchronous output (value X'20') - Specifies that the server is sending unsolicited queued output to the client. This can occur when IMS inserts a message to an alternate PCB. Certain IMS commands, when submitted as commit-then-send, can cause IMS to send the output to a client with this flag set. In this case, the OTMA prefixes contain no identifying information that the client can use to correlate the output to the originating command message. These command output data messages simply identify the transaction-pipe name. IMS can also send some unsolicited error messages with only the transaction-pipe name.

ErrorMessageFollows : String

Error Message Follows (value X'10') - Specifies that an error message follows this message. This flag is set for NAK messages from the server. An additional error message is then sent to the client. The asynchronous-output flag is not set in the error data message, because the output is not generaed by an IMS application.

TChainFlag

Private Attributes:

FirstInChain : String

First-In-Chain (value X'80') - Specifies the first segment in a chain of segments which comprise a multi-segment message. Subsequent segments of the message only need the message-control information

5   section of the message prefix. Other applicable prefix segments (for example, those specified by the client on the transaction message) are sent only with the first segment (with the first-in-chain flag set). If the OTMA message has only one segment, the last-in-chain flag should also be set.

MiddleInChain : String

10   Middle-In-Chain (value X'40') - Specifies a segment that is neither first nor last in a chain of segments that comprise a multi-segment message. These segments only need the message-control information section of the message prefix.

Restriction: Because the client and server tokens are in the state-data

15   section of the message prefix, they cannot be used to correlate and combine segmented messages. The transaction-pipe name and send-sequence numbers can be used for this purpose; they are in the message-control information section of the message prefix for each segment.

LastInChain : String

20   Last-In-Chain (value X'20') - Specifies the last segment of a multi-segment message.

DiscardChain : String

Discard Chain (value X'10') - Specifies that the entire chain of a multi-segment message is to be discarded. The last-in-chain flag must also be

25   set.

TPrefixFlag

Private Attributes:

StateData : String

30   State Data (value X'80') - Specifies that the message includes the state-data section of the message prefix.

127

SecurityData : String

Security (value X'40') - Specifies that the message includes the security-data section of the message prefix.

UserData : String

5   User Data (value X'20') - Specifies that the message includes the user-data section of the message prefix.

ApplicationData : String

Application Data (value X'10') - Specifies that the message includes the application-data section of the message prefix.

10

StateData

StateData

This includes a destination override, map name, synchronization level,

15   commit mode, tokens and server state. Note that this is state data for a transaction. OTMA also supports state data headers for the following: Server Available Command, Client Bid Command, SRVresynch Command, REQresynch Command, REPresynch Command. However, these commands would never be generated by a client device, and so

20   command messages would never come into the IMS Connect interface, and so we do not need to model them.

Private Attributes:

Length : TwoByteField

ServerState : TServerState   Specifies the mode in which the transaction is

25   running.

SynchronizationFlag : TSynchronizationFlag - Specifies the commit mode of the transaction. This flag controls and synchronizes the flow of data between the client and server.

SynchronizationLevel : TSynchronizationLevel - Specifies the

30   transaction synchronization level, the way in which the client and server transaction program (for example, IMS application program) interacts

STL920000075US2

with program output messages. The default is Confirm. IMS always requests a response when sending commit-then-send output to a client.

Reserved : OneByteField

MapName : EightByteField - Specifies the formatting map used by the server to map output data streams (for example, 3270 data streams). Although OTMA does not provide MFS support, you can use the map name to define the output data stream. The name is an 8-byte MOD name that is placed in the I/O PCB. IMS replaces this field in the prefix with the map name in the I/O PCB when the message is inserted. The map name is optional.

ServerToken : SixteenByteField - Specifies the server name. The Server Token must be returned by the client to the server on response messages (ACKs or NAKs). For conversational transactions, the Server Token must also be returned by the client on subsequent conversational input.

CorrelatorToken : SixteenByteField - Specifies a client token to correlate input with output. This token is optional and is not used by the server. Recommendation: Clients should use this token to help manage their transactions.

ContextID : SixteenByteField

Specifies the RRS/MVS token that is used with SYNCLVL=02 and protected conversations.

DestinationOverride : EightByteField - Specifies an LTERM name used to override the LTERM name in the IMS application program's I/O PCB. This override is used if the client does not want to override the LTERM name in the I/O PCB with the transaction-pipe name. This optional override is not used if it begins with a blank.

STL920000075US2

ServerUserDataLength : TwoByteField - Specifies the length of the server user data, if any. The maximum length of the server use data is 256 bytes.

5   ServerUserData : VariableLengthField - Specifies any data needed by the server. If included in a transaction message by the client, it is returned by the server in the output data messages.

10   DefinedTypes

TServerState
       Private Attributes:
       ConversationalState : String
15   Conversational State (value X'80') - Specifies a conversational mode transaction. The server sets this state when processing a conversational-mode transaction. This state is also set by the client when sending subsequent IMS conversational data messages to IMS.
       ResponseMode : String
20   Response Mode (value X'40') - Specifies a response-mode transaction. Set by the server when processing a response-mode transaction. This state has little significance for an OTMA server, because OTMA does not use sessions or terminals.

25   TSynchronizationFlag
       Private Attributes:
       1CommitThenSend : String
       Commit-then-Send (value X'40') - Specifies a commit-then-send transaction. The server commits output before sending it; for example,
30   IMS inserts the output to the IMS message queue.
       SendThenCommit : String

STL920000075US2

Send-then-Commit (value X'20') - Specifies a send-then-commit

transaction. The server sends output to the client before committing it.

TSynchronizationLevel

5   Private Attributes:

None : String

None (value X'00') - Specifies that no synchronization is requested. The

server application program does not request an ACK message when it

sends output to a client. None is only valid for send-then-commit

10   transactions.

Confirm : String

Confirm (value X'01') - Specifies that synchronization is requested. The

server sends transaction output with the response flag set to Response

Requested in the message-control information section of the message

15   prefix. Confirm can be used for either commit-then-send or send-then-

commit transactions.

SYNCPT : String

SYNCPT (value X'02') - Specifies that the programs participate in

coordinated commit processing on resources updated during the

20   conversion under the RRS/MVS recovery platform. A conversation with

this level is also called a protected conversation.

SecurityData

25   SecurityData

This includes the user ID, user token, and security flags.

The security-data section is mandatory for every transaction, and can be

present for OTMA command messages.

Private Attributes:

30   Length : TwoByteField - Specifies the length of the security data section

of the message prefix, including the length field.

131

SecurityFlag : TSecurityFlag - Specifies the type of security checking to be performed. It is assumed that the user ID and password are already verified.

5   LengthOfSecurityFields : OneByteField - Specifies the length of the security data fields: User ID, Profile, and Utoken. These three fields can appear in any order, or they can be omitted. Each has the following structure: Length field, then Field type, then Data field. The actual length of the User ID or Profile should not be less than the value specified for the

10   length of each field. Length can be 0.

tokenLength : OneByteField

Specifies the length of the user token.

Length does not include length field itself.

15   UtokenType : OneByteField - Specifies that this field contains a user token. (Value X'00')

Utoken : VariableLengthField - Specifies the user token. The user ID and profile are used to create the user token. The user token is passed along to the IMS dependent region. If the client has already called FACF, it should

20   pass the Utoken with field type X'00' so that RACF is not called again. Variable length, from 1 to 80 bytes.

UserIDLength : OneByteField - Specifies the length of the user ID.

Length does not include length field itself.

UserIDType : OneByteField. Specifies that this field contains a user ID.

25   (Value X'02').

UserID : VariableLengthField - Specifies the actual user ID.

Variable length, from 1 to 10 bytes.

ProfileLength : OneByteField. Specifies the length of the profile. Length does not include length field itself.

30   ProfileType : OneByteField Specifies that this field contains a profile. (Value X'03').

132

Profile : VariableLengthField. Specifies the system authorization facility (SAF) profile. For RACF, thiis is the group name.

Variable length, from 1 to 10 bytes.

5   DefinedTypes

TSecurityFlag

Private Attributes:

NoSecurity : String

10   No Security (value X'N') - Specifies that no security checking is to be done.

Check : String

Check (value X'C') - Specifies that transaction and command security checking is to be performed.

15   Full : String

Full (value X'F')

Specifies that transaction, command, and MPP region security checking is to be performed.

20   UserData

UserData

This includes any special information needed by the client.

The user-data section is variable length and follows the security-data

25   section of the message prefix. It can contain any data.

Private Attributes:

Length : TwoByteField

Specifies the length of the user-data section of the message prefix, including the length field. The maximum length of the user data is 1024

30   bytes.

UserData : VariableLengthField

133

Specifies the optional user data. This data is managed by the client, and can be created and updated using the DFSYDRU0 exit routine. The server returns this section unchanged to the client as the first segment of any output messages.

5

Primitives

OneByteField

TwoByteField

10 FourByteField

EightByteField

SixteenByteField

SixByteField

VariableLengthField

15

ApplicationData

ApplicationData

The application data class contains all the message data except for LL, ZZ,

20 and the transaction code.

Note: this model does not capture the notion of message segments. When using this model you have to bear in mind whether the system you are using has any limitations such as a maximum segment size. IMS connectors (via OTMA or SNA) must support the capability of breaking

25 the "application data" into IMS message segments. For instance, if you are sending this XML message directly to the IMS message queue and if the message queue has a 32k limit, then you have to take your XML message and break it up into 32k chunks. The application on IMS will then have to gather up the 32k chunks one by one. IMS new applications that receive

30 XML documents directly, must be capable of receiving XML documents

134

in multiple segments. For ACK or NAK messages, there is no application data included in the message.

Field

5   Each data field, defined in a copybook for the application data, will be associated with type descriptor for data types.

6.   b.   CICS BMS (Basic Mapping Support) Metamodel

10   FIGURE 35 illustrates a BMS language metamodel, which is usable by application programs to define data structures which represent connector interfaces. FIGURE 36 illustrates attributes, fields, attribute values, maps, and attributes of the BMS Language Model. FIGURE 36 illustrates attributes, fields, attribute values, maps, and attributes of the BMSMetamodel.

15   BMSFieldAttributes
           Private Attributes:
           justify : justifyValues
           attrb : attrbValues
           color : colorValue = "DEFAULT"

BMSMap
           Implemented by DFHMDI macro
30   MAPNAME is the name of the map and consists of 1-7 characters.
               COLUMN specifies the column in a line at which the map is to be placed, that is, it establishes the left or right map margin.
               JUSTIFY controls whether map and page margin selection and column counting are to be from the left or right side of the page. The
35   columns between the specified map margin and the page margin are not available for subsequent use on the page for any lines included in the map.

               NUMBER   is the column from the left or right page margin where the left or right map margin is to be established.

135

STL920000075US2

NEXTindicates that the left or right map margin is to be placed in the next available column from the left or right on the current line.

SAME indicates that the left or right map margin is to be established in the same column as the last nonheader or
nontrailer map used that specified COLUMN=number and the same JUSTIFY operands as this macro. For input operations, the map is positioned at the extreme left-hand or right-hand side, depending on whether JUSTIFY=LEFT or JUSTIFY=RIGHT has been specified.

LINE specifies the starting line on a page in which data for a map is to be formatted.

NUMBER is a value in the range 1-240, specifying a starting line number. A request to map, on a line and column, data that has been formatted in response to a preceding BMS command, causes the current page to be treated as though complete. The new data is formatted at the requested line and column on a new page.

NEXT specifies that formatting of data is to begin on the next available completely empty line. If LINE=NEXT is specified in the DFHMDI macro, it is ignored for input operations and LINE=1 is assumed.

SAME specifies that formatting of data is to begin on the same line as that used for a preceding BMS command. If COLUMN=NEXT is specified, it is ignored for input operations and COLUMN=1 is assumed. If the data does not fit on the same line, it is placed on the next available line that is completely empty.

SIZE(arg1,arg2) specifies the size of a map. arg2 = line is a value in the range 1-240, specifying the depth of a map as a number of lines. arg1 = column is a value in the range 1-240, specifying the width of a map as a number of columns.
This operand is required in the following cases:
An associated DFHMDF macro with the POS operand is used.

The map is to be referred to in a SEND MAP command with the ACCUM option.

The map is to be used when referring to input data from other than a 3270 terminal in a RECEIVE MAP command.

SOSI indicates that the field may contain a mixture of EBCDIC and DBCS data. The DBCS subfields within an EBCDIC field are

136

delimited by SO (shift out) and SI (shift in) characters. SO and SI both occupy a single screen position (normally displayed as a blank). They can be included in any non-DBCS field on output, if they are correctly paired. The terminal user can transmit them inbound if they are

5   already present in the field, but can add them to an EBCDIC field only if the field has the SOSI attribute.

TIOAPFX specifies whether BMS should include a filler in the

10   symbolic description maps to allow for the unused TIOA prefix. This operand overrides the TIOAPFX operand specified for the DFHMSD macro.

YES specifies that the filler should be included in the symbolic

15   description maps. If TIOAPFX=YES is specified, all maps within the mapset have the filler. TIOAPFX=YES should always be used for command-level application programs.

NO is the default and specifies that the filler is not to be included.

BMSMapset
30   Implemented by the DFHMSD macro
Programming attributes in this class

type=DSECT | MAP | FINAL. Mandatory, this generates the two bits of a
BMS entity

35

mode=OUT | IN | INOUT. OUT is default. INOUT says do both IN and
OUT processing. With IN, I is appended to mapname, with OUT, O is
appended to mapname

40   lang=ASM| COBOL | COBOL2 | PLI | C. ASM is default.

fold=LOWER | UPPER. LOWER is default. Only applies to C.

dsect=ADS | ADSL. ADS is default. ADSL requires lang = C.

45

trigraph = YES only applies to lang = C.

138

BASE specifies that the same storage base is used for the symbolic description maps from more than one mapset. The same name is specified for each mapset that is to share the same storage base.

Because all mapsets with the same base describe the same storage, data related to a previously used mapset may be overwritten when a new mapset is used. Different maps within the same mapset also overlay one another.

This operand is not valid for assembler-language programs, and cannot be used when STORAGE=AUTO has been specified.

term = type. Each terminal type is represented by a character. 3270 is default and is a blank. Added to MAPSET name, or, suffix = numchar which is also added to mapset name.

CURSLOC indicates that for all RECEIVE MAP operations using this map on 3270 terminals, BMS sets a flag in the application data structure element for the field where the cursor is located.

STORAGE
The meaning of this operand depends upon the language in which application programs are written, as follows:

For a COBOL program, STORAGE=AUTO specifies that the symbolic description maps in the mapset are to occupy separate (that is, not redefined) areas of storage. This operand is used when the symbolic description maps are copied into the working-storage section and the storage for the separate maps in the mapset is to be used concurrently.

For a C program, STORAGE=AUTO specifies that the symbolic description maps are to be defined as having the automatic storage class. If STORAGE=AUTO is not specified, they are declared as pointers. You cannot specify both BASE=name and STORAGE=AUTO for the same mapset.

If STORAGE=AUTO is specified and TIOAPFX is not, TIOAPFX=YES is assumed.

For a PL/I program, STORAGE=AUTO specifies that the symbolic description maps are to be declared as having the AUTOMATIC storage class. If STORAGE=AUTO is not specified, they are declared as BASED. You cannot specify both BASE=name and STORAGE=AUTO for the same mapset. If STORAGE=AUTO is specified and TIOAPFX is not, TIOAPFX=YES is assumed.

STL920000075US2

For an assembler-language program, STORAGE=AUTO specifies that individual maps within a mapset are to occupy separate areas of storage instead of overlaying one another.

BMSField
40   Implemented by the DFHMDF macro.
    GRPNAME is the name used to generate symbolic storage definitions and to combine specific fields under one group name. The same group name must be specified for each field that is to belong to the group. The length of the name is up to 30 characters though you should

140

refer to your compiler manual to make sure that there are no other
restrictions on the length.

If this operand is specified, the OCCURS operand cannot be
specified.

The fields in a group must follow on; there can be gaps between them,
but not other fields from outside the group. A field name must be
specified for every field that belongs to the group, and the POS operand
must also be specified to ensure that the fields follow each other. All the
DFHMDF macros defining the fields of a group must be placed together,
and in the correct order (ascending numeric order of the POS value).

For example, the first 20 columns of the first six lines of a map can be
defined as a group of six fields, as long as the remaining columns on the
first five lines are not defined as fields.

The ATTRB operand specified on the first field of the group applies
to all of the fields within the group.

LENGTH specifies the length (1-256 bytes) of the field or group of
fields. This length should be the maximum length required for application
program data to be entered into the field; it should not include the one-
byte attribute indicator appended to the field by CICS for use in
subsequent processing. The length of each individual subfield within a
group must not exceed 256 bytes. LENGTH can be omitted if PICIN or
PICOUT is specified, but is required otherwise. You can specify a length
of zero only if you omit the label (field name) from the DFHMDF macro.
That is, the field is not part of the application data structure and the
application program cannot modify the attributes of the field. You can use
a field with zero length to delimit an input field on a map.

The map dimensions specified in the SIZE operand of the DFHMDI
macro defining a map can be smaller than the actual page size or screen
size defined for the terminal.

If the LENGTH specification in a DFHMDF macro causes the map-
defined boundary on the same line to be exceeded, the field on the output
screen is continued by wrapping.

OCCURS specifies that the indicated number of entries for the field
are to be generated in a map, and that the map definition is to be generated
in such a way that the fields are addressable as entries in a matrix or an
array. This permits several data fields to be addressed by the same name
(subscripted) without generating a unique name for each
field.

141

OCCURS and GRPNAME are mutually exclusive; that is, OCCURS cannot be used when fields have been defined under a group name. If this operand is omitted, a value of OCCURS=1 is assumed.

PICIN (COBOL and PL/I only) specifies a picture to be applied to an input field in an IN or INOUT map; this picture serves as an editing specification that is passed to the application program, thus permitting the user to exploit the
editing capabilities of COBOL or PL/I. BMS checks that the specified characters are valid picture specifications for the language of the map.

However, the validity of the input data is not checked by BMS or the high-level language when the map is used, so any desired checking must be performed by the application program. The length of the data associated with "value" should be the same as that specified in the LENGTH operand if LENGTH is specified. If both PICIN and PICOUT are used, an error message is produced if their calculated lengths do not agree; the shorter of the two lengths is used. If PICIN or PICOUT is not coded for the field definition, a character definition of the field is automatically generated regardless of other operands that are coded, such as ATTRB=NUM.
Note: The valid picture values for COBOL input maps are:

A P S V X 9 / and (

The valid picture values for PL/I input maps are:

A B E F G H I K M P R S T V X Y and Z

1 2 3 6 7 8 9 / + - , . * $ and (

For PL/I, a currency symbol can be used as a picture character. The symbol can be any sequence of characters enclosed in < and >, for example <DM>.

Refer to the appropriate language reference manual for the correct syntax of the PICTURE attribute.

PICOUT (COBOL and PL/I only) is similar to PICIN, except that a picture to be applied to an output field in the OUT or INOUT map is generated.

The valid picture values for COBOL output maps are:

A B E P S V X Z 0 9 , . + - $ CR DB / and (

142

The valid picture values for PL/I output maps are:

A B E F G H I K M P R S T V X Y and Z

1 2 3 6 7 8 9 / + - , . * $ CR DB and (

For PL/I, a currency symbol can be used as a picture character. The symbol can be any sequence of characters enclosed in < and >, for example <DM>.

Refer to the appropriate language reference manual for the correct syntax of the PICTURE attribute.

Note: COBOL supports multiple currency signs and multi-character currency signs in PICTURE specifications.

The default currency picture symbol is the dollar sign ($),which represents the national currency symbol; for example the dollar ($), the pound (£), or the yen (¥).

The default currency picture symbol may be replaced by a different currency picture symbol that is defined in the   SPECIAL NAMES clause. The currency sign represented by the picture symbol is defined in the same clause. For example:

```
SPECIAL NAMES.
CURRENCY SIGN IS '$' WITH PICTURE SYMBOL '$'.
CURRENCY SIGN IS '£' WITH PICTURE SYMBOL '£'.
CURRENCY SIGN IS 'EUR' WITH PICTURE SYMBOL '#'.

WORKING STORAGE SECTION.
    01 USPRICE PIC $99.99.
    01 UKPRICE PIC £99.99.
    01 ECPRICE PIC #99.99.
```

LENGTH must be specified when PICOUT specifies a COBOL picture containing a currency symbol that will be replaced by a currency sign of length greater than 1.

POS specifies the location of a field. This operand specifies the individually addressable character location in a map at which the attribute byte that precedes the field is positioned.

143

number specifies the displacement (relative to zero) from the beginning of the map being defined.

(line,column) specify lines and columns (relative to one) within the map being defined.

The location of data on the output medium is also dependent on DFHMDI operands.

The first position of a field is reserved for an attribute byte. When supplying data for input mapping from non-3270 devices, the input data must allow space for this attribute byte. Input data must not start in column 1 but may start in column 2.

The POS operand always contains the location of the first position in a field, which is normally the attribute byte when communicating with the 3270. For the second and subsequent fields of a group, the POS operand points to an assumed attribute-byte position, ahead of the start of the data, even though no actual attribute byte is necessary. If the fields follow on immediately from one another, the POS operand should point to the last character position in the previous field in the group.

When a position number is specified that represents the last character position in the 3270, two special rules apply:

ATTRIB=IC should not be coded. The cursor can be set to location zero by using the CURSOR option of a SEND MAP, SEND CONTROL, or SEND TEXT command.

If the field is to be used in an output mapping operation with MAP=DATAONLY on the SEND MAP command, an attribute byte for that field must be supplied in the symbolic map data structure by the application program.

PS specifies that programmed symbols are to be used. This overrides any PS operand set by the DFHMDI macro or the DFHMSD macro.

BASE is the default and specifies that the base symbol set is to be used.

psid specifies a single EBCDIC character, or a hexadecimal code of the form X'nn', that identifies the set of programmed symbols to be used.

144

The PS operand is ignored unless the terminal supports programmed symbols.

SOSI indicates that the field may contain a mixture of EBCDIC and DBCS data. The DBCS subfields within an EBCDIC field are delimited by SO (shift out) and SI (shift in) characters. SO and SI both occupy a single screen position (normally displayed as a blank). They can be included in any non-DBCS field on output, if they are correctly paired. The terminal user can transmit them inbound if they are already present in the field, but can add them to an EBCDIC field only if the field has the SOSI attribute.

TRANSP determines whether the background of an alphanumeric field is transparent or opaque, that is, whether an underlying (graphic) presentation space is visible between the characters.

- VERSID
- VT
- VTAB

Derived from MFSStatement

Private Attributes:
card : String
    CARD attribute

147

120|126|132
Specifies line length for 3284, and 3286 device types (TYPE=3270P).

CARD
Specifies that the device has a 3270 operator identification card reader.
NOCD specifies the absence of the CARD feature.

DEKYBD
Specifies data entry keyboard feature. This feature implies PFK feature;
therefore, PFK is invalid if DEKYBD is specified. NOPFK implies the
absence of PFK and DEKYBD features.

PFK
Specifies that the device has program function keys. NOPFK specifies the
absence of the PFK and DEKYBD features.

PEN
Specifies the selector light pen detect feature. NOPEN specifies the
absence of the PEN feature.

1|2|3|4|5|6|7|8|9|10
Specifies customer-defined features for the 3270P device type.

For 3270P devices, FEAT= allows grouping of devices with special device
characteristics. For example, FEAT=1 could group devices with a
maximum of 80 print positions and no VFC, and FEAT=2 could group
devices with 132 print positions and the VFC feature. FEAT=IGNORE
should be specified to group together devices with a minimum set of
device capabilities. When WIDTH= is specified, FEAT=(1...10) must also
be specified. If FEAT=(1...10) is specified but WIDTH= is not specified,
WIDTH= defaults to 120.

When IGNORE is specified, no other values should be coded in the
FEAT= operand. When FEAT=IGNORE is not specified in the
TERMINAL macro during system definition, the MSG statement must
specify IGNORE in the SOR= operand for the device format with the
IGNORE specification. Unless FEAT=IGNORE is used, FEAT= must
specify exactly what was specified in the TERMINAL macro during IMS
system definition. If it does not, the DFS057 error message is issued.
When FEAT=IGNORE or 1-10 is specified for 3270 devices, the operands
PEN=, CARD=, and PFK= can still be specified. When TYPE=3270P and
FEAT=IGNORE, MFS allows a line width of 120 characters.

CARD, PFK, DEKYBD, and PEN feature values are valid only for 3270
displays. If the FEAT= operand is omitted, the default features are CARD,
PFK, and PEN for

149

STL920000075US2

3270 displays; the default line width is 120 for TYPE=3270P.

1, 2, 3, 4, 5, 6, 7, 8, 9, and 10 are valid values only for 3270, 3270P and 3270-An. For 3270 displays, the FEAT= specifications of 1 to 5 can be used to group devices with specific features or hardware data stream dependencies.

Restriction: This keyword is optional and cannot be used with any other feature specification for 3270 displays.

Feature operand values can be specified in any order, and only those values desired need be specified. The underlined values do not have to be specified because they are defaults. Only one value in each vertical list can be specified.

page : MFSPageType
PAGE attribute

Specifies output parameters as follows:

number
For printer devices, number defines the number of print lines on a printed page; for card devices, number defines the number of cards to be punched per DPAGE or physical page (if pp parameter is used in the DFLD statements). This value is used for validity checking. The number specified must be greater than or equal to 1 and less than 256. The default is 55.

DEFN
Specifies that lines/cards are to be printed/punched as defined by DFLD statements (no lines/cards are to be removed or added to the output page).

SPACE
Specifies that each output page contains the exact number of lines/cards specified in the number parameter.

FLOAT
Specifies that lines/cards with no data (all blank or NULL) after formatting are to be deleted.

For 3270P devices, some lines having no data (that is, all blank or null) must not be deleted under the following circumstances:

The line contains one or more set line density (SLDx=) specifications.

A field specified as having extended attributes spans more than one line.

150

pen : String
> PEN attribute

> Defines an input field name to contain literal data when an immediate light
> pen detection of a field with a space or null designator character occurs.
> The literal data is defined on the DFLD statement with the PEN= operand.
> (See PEN= operand on the DFLD statement.) This name can be referred to
> by an MFLD statement and must not be used as the label of a DFLD
> statement within this DEV definition. The PEN= operand is valid only for
> 3270 displays. If FEAT=NOPEN is specified, it is changed to PEN.

> If an immediate detect occurs on a field defined with a space or null
> designator character, and either another field has been selected or
> modified or has the MOD attribute, or the PEN= operand is not defined
> for the DFLD, a question mark (?) is inserted in the PEN= field name.

> If no immediate detection occurs or the immediate detect occurs on a field
> defined with an ampersand (&) designator character, the PEN= operand is
> padded with the fill specified in the MFLD statement.

pfk : MFSFunctionKeyType
> PFK attribute

> Defines an input field name to contain program function key literal or
> control function data (first subparameter) and, in positional or keyword
> format, either the literal data to be placed in the specified field, or the
> control function to be performed when the corresponding function key is
> entered (remaining subparameters).

> The name of the first subparameter (the input field name that will contain
> the program function key literal or control function data) can be referred to
> by an MFLD statement and must not be used as the label of a DFLD
> statement within this DEV definition. The remaining subparameters can be
> specified in positional or keyword format. If the subparameters are in
> keyword format, the integer specified must be from 1 to 36, inclusive, and
> not duplicated. Only one PFK= operand format (positional or keyword)
> can be specified on a DEV statement. This operand is valid only for 3270
> displays. At the time the actual
> format blocks are created, each literal is padded on the right with blanks to
> the length of the largest literal in the list. The maximum literal length is
> 256 bytes.

> If the device supports the IMS copy function, then PFK12 invokes the
> copy function and the definition of PFK12 in the DEV statement is
> ignored; otherwise, the definition of PFK12 is honored.

151

If FEAT=NOPFK is specified, it is changed to PFK. The maximum number of user-defined PFKs is 36.

Control functions that can be specified are:

5

NEXTPP--PAGE ADVANCE
Specifies a request for the next physical page in the current output message. If no output message is in progress, no explicit response is made.

10

NEXTMSG--MESSAGE ADVANCE
Specifies a request to dequeue the output message in progress (if any) and to send the next output message in the queue (if any).

NEXTMSGP--MESSAGE ADVANCE PROTECT
15

Specifies a request to dequeue the output message in progress (if any), and send the next output message or return an information message indicating that no next message exists.

NEXTLP--NEXT LOGICAL PAGE
20

Specifies a request for the next logical page of the current message.

ENDMPPI--END MULTIPLE PAGE INPUT
Specifies the end of a multiple physical page input message.

substitution : String
25

SUB attribute

Specifies the character used by MFS to replace any X'3F' characters in the input data stream. No translation occurs if this parameter is specified as X'3F' or this parameter is not specified, or the input

30

received bypasses MFS editing. The specified SUB character should not appear elsewhere in the data stream; therefore, it should be nongraphic.

X'hh'
Character whose hexadecimal representation is 'hh' replaces all X'3F' in

35

the input data stream.

C'c'
Character 'c' replaces all X'3F' in the input data stream.

type : String
40

TYPE attribute

Specifies the device type and model number of a device using this format description. The 3284-3 printer attached to a 3275 is supported only as TYPE=3270P. The model number specified when defining a format for a

45

3284-3 is the model number of the associated 3275.

152

TYPE=3270-An specifies a symbolic name for 3270 and SLU 2 displays with the screen size defined during IMS system definition, feature numbers n=1-15. This specification causes the MFS Language utility to read the MFS device characteristics table (DFSUDT0x) to extract the screen size.

width : int
WIDTH attribute

Specifies the maximum line width for this DEV type as one of:

- Number of print positions per line of input or output data
- Number of punch positions per card of input or output data
- Card width for card reader input data

The default is 120 for 3270P output. Line width is specified relative to column 1, regardless of whether a left margin value is specified in the HTAB= keyword. The width specified must be greater than or equal to 1.

For 3270P devices, if WIDTH is specified, then FEAT=(1...10) must also be specified. If FEAT=(1...10) is specified, and WIDTH= is not specified, WIDTH= defaults to 120.

MFSMessageDescriptor
MSG statement

The MSG statement initiates and names a message input or output definition.

Unsupported attributes:
- All attributes are supported
Derived from MFSStatement

Private Attributes:
fill : String
FILL attribute

Specifies a fill character for output device fields. This operand is valid only if TYPE=OUTPUT. The default is C' '. The fill specification is ignored unless FILL=NONE is specified on the DPAGE statement in the FMT definition. For 3270 output when EGCS fields are present, only FILL=PT or FILL=NULL should be specified. A FILL=PT erases an output field (either a 1- or 2-byte field) only when data is sent to the field, and thus does not erase the DFLD if the application program message omits the MFLD.

153

C'c'

Character 'c' is used to fill device fields. For 3270 display devices, any specification with a value less than X'3F' is changed to X'00' for control characters or to X'40' for other nongraphic characters. For all other devices, any FILL=C'c' specification with a value less than X'3F' is ignored and defaulted to X'3F' (which is equivalent to a specification of FILL=NULL).

NULL

Specifies that fields are not to be filled.

PT

Is identical to NULL except for 3270 display. For 3270 display, PT specifies that output fields that do not fill the device field (DFLD) are followed by a program tab character to erase data previously in the field.

ignoreSource : boolean

SOR attribute

Specifies the source name of the FMT statement which, with the DEV statement, defines the terminal or remote program data fields processed by this message descriptor. Specifying IGNORE for TYPE=OUTPUT causes MFS to use data fields specified for the device whose FEAT= operand specifies IGNORE in the device format definition. For TYPE=INPUT, IGNORE should be specified only if the corresponding message output descriptor specified IGNORE. If you use SOR=IGNORE, you must specify IGNORE on both the message input descriptor and the message output descriptor.

option : int

OPT attribute

Specifies the message formatting option used by MFS to edit messages. The default is 1.

paging : boolean

PAGE attribute

Specifies whether (YES) or not (NO) operator logical paging (forward and backward paging) is to be provided for messages edited using this control block. This operand is valid only if TYPE=OUTPUT. The default is NO, which means that only forward paging of physical pages is provided.

type : MFSDescriptorType

TYPE attribute

Defines this definition as a message INPUT or OUTPUT control block. The default is INPUT.

MFSLogicalPage
LPAGE statement

The optional LPAGE statement defines a group of segments comprising a logical page. It is implied if not present.

Unsupported attributes:
- All attributes are supported
Derived from MFSStatement

Private Attributes:
condition : MFSConditionType
COND attribute

Describes a conditional test that, if successful, specifies that the segment and field definitions following this LPAGE are to be used for output editing of this logical page. The specified portion of the first segment of a logical page is examined to determine if it is greater than (>), less than (<), greater than or equal to (°), less than or equal to (°), equal to (=), or not equal to (ne) the specified literal value to determine if this LPAGE is to be used for editing. COND= is not required for the last LPAGE statement in the MSG definition.

The area examined can be defined by a field name (mfldname), an offset in a field (mfldname(pp) where pp is the offset in the named field), or an offset in the segment (segoffset). If the mfldname(pp) form is used, pp must be greater than or equal to 1. The length of the compare is the length of the specified literal. If OPT=3 is specified on the previous MSG statement, the area to be examined must be within one field as defined on an MFLD statement.

If segoffset is used, it is relative to zero, and the specification of that offset must allow for LLZZ of the segment (that is, the first data byte is at offset 4).

If pp is used, the offset is relative to 1 with respect to the named field (that is, the first byte of data in the field is at offset 1, not zero).

If the mfldname specified is defined with ATTR=YES, the pp offset must be used. The minimum offset specified must be 3. That is, the first byte of data in the field is at offset 3, following the two bytes of attributes.

If ATTR=nn is specified, the minimum offset must be one plus twice nn. Thus, if ATTR=2 is specified, pp must be at least 5, and, if ATTR=(YES,2) is specified, pp must be at least 7.

155

If the conditional tests for all LPAGEs fail, the last LPAGE in this MSG definition is used for editing.

If LPAGE selection is to be specified using the command data field, that is, /FORMAT modname...(data), the MFLD specified in the LPAGE COND=mfldname parameter should be within the first 8 bytes of the associated LPAGEs of the MOD.

promptValue : String

MFSSegment
SEG statement

The SEG statement delineates message segments and is required only if multisegment message processing is required by the application program. Output message segments cannot exceed your specified queue buffer length. Only one segment should be defined for TYPE=INPUT MSGs when the input message destination is defined as a single segment command or transaction. If more than one segment is defined, and the definition is used to input a single segment command or transaction, care must be used to ensure that your input produces only one segment after editing. It is implied if not present.

Unsupported attributes:
 - All attributes are supported
Derived from MFSStatement

Private Attributes:
exit : MFSExitType
EXIT attribute

Describes the segment edit exit routine interface for this message segment. exitnum is the exit routine number and exitvect is a value to be passed to the exit routine when it is invoked for this segment. exitnum can range from 0 to 127. exitvect can range from 0 to 255. The SEG exit is invoked when processing completes for the input segment.

graphic : boolean
GRAPHIC attribute

Specifies for MSG TYPE=INPUT whether (YES) or not (NO) IMS should perform upper case translation on this segment if the destination definition requests it (see the EDIT= parameter of the TRANSACT or NAME macro). The default is YES. If input segment data is in nongraphic format (packed decimal, EGCS, binary, and so forth), GRAPHIC=NO should be

156

specified. When GRAPHIC=NO is specified, FILL=NULL is invalid for MFLDs within this segment.

The list below shows the translation that occurs when GRAPHIC=YES is specified and the input message destination is defined as requesting upper case translation:

Before Translation After Translation

a through z
   A through Z

X'81' through X'89'
   X'C1' through X'C9'

X'91' through X'99'
   X'D1' through X'D9'

X'A2' through X'A9'
   X'E2' through X'E9'

If FILL=NULL is specified for any MFLD in a segment defined as GRAPHIC=YES, the hexadecimal character X'3F' is compressed out of the segment. If GRAPHIC=NO and FILL=NULL are specified in the SEG statement, any X'3F' in the non-graphic data stream is compressed out of the segment and undesirable results might be produced. Non-graphic data should be sent on output as fixed length output fields and the use of FILL=NULL is not recommended in this case.

For MSG TYPE=OUTPUT, the GRAPHIC= keyword applies only for DPM. It specifies whether (YES) or not (NO) nongraphic control characters (X'00' to X'3F') in the data from the IMS application program are to be replaced by blanks. The default value is YES. If NO is specified, MFS allows any bit string received from an IMS application program to flow unmodified through MFS to the remote program.

Restriction: When GRAPHIC=NO is specified, IMS application programs using Options 1 and 2 cannot omit segments in the middle of an LPAGE, or truncate or omit fields in the segment using the null character (X'3F').

MFSMessageField
MFLD statement

The MFLD statement defines a message field as it will be presented to an application program as part of a message output segment. At least one MFLD statement must be specified for each MSG definition.

5

Unsupported attributes:
- All attributes are supported
Derived from MFSStatement

Private Attributes:
10   **attributes : boolean**
       ATTR attribute

       Specifies whether (YES) or not (NO) the application program can modify the 3270 attributes and the extended attributes (nn).

15
       If YES, 2 bytes must be reserved for the 3270 attribute data to be filled in by the application program on output and to be initialized to blanks on input. These 2 bytes must be included in the LTH= specification.

20
       The value supplied for nn is the number of extended attributes that can be dynamically modified. The value of nn can be a number from 1 to 6. An invalid specification will default to 1. Two additional bytes per attribute must be reserved for the extended attribute data to be filled in by the application program on output and to be initialized to blanks on input.
25   These attribute bytes must be included in the MFLD LTH= specification.

       Example: Shown below are valid specifications for ATTR= and the number of bytes that must be reserved for each different specification:

30
       MFLD ,ATTR=(YES,nn)
           2 + (2 × nn)

       MFLD ,ATTR=(NO,nn)
35   2 × nn

       MFLD ,ATTR=(nn)
           2 × nn

40   MFLD ,ATTR=YES
           2

       MFLD ,ATTR=NO
           0

45

ATTR=YES and nn are invalid if a literal value has been specified through the positional parameter in an output message.

The attributes in a field sent to another IMS ISC subsystem are treated as input data by MFS regardless of any ATTR= specifications in the format of the receiving subsystem. For example, a message field (MFLD) defined as ATTR=(YES,1),LTH=5 would contain the following:

00A0C2F1C8C5D3D3D6

If the MFLD in the receiving subsystem is defined as LTH=9 and without ATTR=, the application program receives:

00A0C2F1C8C5D3D3D6

If the MFLD in the receiving subsystem is defined as LTH=13 and ATTR=(YES,1), the application program receives:

4040404000A0C2F1C8C5D3D3D6

If the MFLD in the receiving subsystem is defined as LTH=5 and ATTR=(YES,1), the application program receives:

4040404000A0C2F1C8

The input SEG statement should be specified as GRAPHIC=NO to prevent translation of the attribute data to uppercase.

exit : MFSExitType
EXIT attribute

Describes the field edit exit routine interface for this message field. The exit routine number is specified in exitnum, and exitvect is a value to be passed to the exit routine when it is invoked for this field. The value of exitnum can range from 0 to 127. The value of exitvect can range from 0 to 255. The address of the field as it exists after MFS editing, (but before NULL compression for option 1 and 2), is passed to the edit exit routine, along with the vector defined for the field. (If NOFLDEXIT is specified for a DPM device, the exit routine will not be invoked.) The exit routine can return a code with a value from 0 to 255. MFS maintains the highest such code returned for each segment for use by the segment edit routine. EXIT= is invalid if 'literal' is specified on the same MFLD statement.

extendedAttributes : int
ATTR attribute

Specifies whether (YES) or not (NO) the application program can modify the 3270 attributes and the extended attributes (nn).

159

If YES, 2 bytes must be reserved for the 3270 attribute data to be filled in by the application program on output and to be initialized to blanks on input. These 2 bytes must be included in the LTH= specification.

The value supplied for nn is the number of extended attributes that can be dynamically modified. The value of nn can be a number from 1 to 6. An invalid specification will default to 1. Two additional bytes per attribute must be reserved for the extended attribute data to be filled in by the application program on output and to be initialized to blanks on input. These attribute bytes must be included in the MFLD LTH= specification.

Example: Shown below are valid specifications for ATTR= and the number of bytes that must be reserved for each different specification:

MFLD ,ATTR=(YES,nn)
    $2 + (2 \times nn)$

MFLD ,ATTR=(NO,nn)
    $2 \times nn$

MFLD ,ATTR=(nn)
    $2 \times nn$

MFLD ,ATTR=YES
    2

MFLD ,ATTR=NO
    0

ATTR=YES and nn are invalid if a literal value has been specified through the positional parameter in an output message.

The attributes in a field sent to another IMS ISC subsystem are treated as input data by MFS regardless of any ATTR= specifications in the format of the receiving subsystem. For example, a message field (MFLD) defined as ATTR=(YES,1),LTH=5 would contain the following:

00A0C2F1C8C5D3D3D6

If the MFLD in the receiving subsystem is defined as LTH=9 and without ATTR=, the application program receives:

00A0C2F1C8C5D3D3D6

If the MFLD in the receiving subsystem is defined as LTH=13 and ATTR=(YES,1), the application program receives:

4040404000A0C2F1C8C5D3D3D6

If the MFLD in the receiving subsystem is defined as LTH=5 and ATTR=(YES,1), the application program receives:

4040404000A0C2F1C8

The input SEG statement should be specified as GRAPHIC=NO to prevent translation of the attribute data to uppercase.

fill : String
FILL attribute

Specifies a character to be used to pad this field when the length of the data received from the device is less than the length of this field. This character is also used to pad when no data is received for this field (except when MSG statement specifies option 3.) This operand is only valid if TYPE=INPUT. The default is X'40'.

X'hh'
Character whose hexadecimal representation is hh is used to fill fields. FILL=X'3F' is the same as FILL=NULL.

C'c'
Character c is used to fill fields.

NULL
Causes compression of the message segment to the left by the amount of missing data in the field.

justify : MFSJustifyType
JUST attribute

Specifies that the data field is to be left-justified (L) or right-justified (R) and right- or left- truncated as required, depending upon the amount of data expected or presented by the device format control block.
The default is L.

length : MFSLengthType
LTH attribute

Can be omitted if a literal is specified in the positional operand (TYPE=INPUT), in which case, length specified for literal is used. If LTH= is specified for a literal field, the specified literal is either truncated or padded with blanks to the specified length. If the MFLD statement

161

appears between a DO and an ENDDO statement, a length value is printed on the generated MFLD statement, regardless of whether LTH= is specified in the MFLD source statement.

value : String

value attribute

This corresponds to the 'literal' field in the following description.

The device field name is specified via the 'deviceFields' relationship.

Specifies the device field name (defined via the DEV or DFLD statement) from which input data is extracted or into which output data is placed. If this parameter is omitted when defining a message output control block, the data supplied by the application program is not displayed on the output device. If the repetitive generation function of MFS is used (DO and ENDDO statements), dfldname should be restricted to 6 characters maximum length. When each repetition of the statement is generated, a 2-character sequence number (01 to 99) is appended to dfldname. If the dfldname specified here is greater than 6 bytes and repetitive generation is used, dfldname is truncated at 6 characters and a 2-character sequence number is appended to form an 8-character name. No error message is provided if this
occurs. This parameter can be specified in one of the following formats:

dfldname
Identifies the device field name from which input data is extracted or into which output data is placed.

'literal'
Can be specified if a literal value is to be inserted in an input message.

(dfldname,'literal')
If TYPE=OUTPUT, this describes the literal data to be placed in the named DFLD. When this form is specified, space for the literal must not be allocated in the output message segment supplied by the application program.

If TYPE=INPUT, this describes the literal data to be placed in the message field when no data for this field is received from the device. If this dfldname is used in the PFK parameter of a DEV statement, this literal is always replaced by the PF key literal or control function. However, when this dfldname is specified in the PFK parameter, but the PF key is not used, the literal specified in the MFLD statement is moved into the message field. When physical paging is used, the literal is inserted in the field but is not processed until after the last physical page of the logical page has been displayed.

STL920000075US2

In both cases, if the LTH= operand is specified, the length of the literal is truncated or padded as necessary to the length of the LTH= specification. If the length of the specified literal is less than the defined field length, the literal is padded with blanks if TYPE=OUTPUT and with the specified fill character (FILL=) if TYPE=INPUT. If no fill character is specified for input, the literal is padded with blanks (the default). The length of the literal value cannot exceed 256 bytes.

(dfldname,system-literal)
Specifies a name from a list of system literals. A system literal functions like a normal literal except that the literal value is created during formatting prior to transmission to the device. The LTH=, ATTR=, and JUST= operands cannot be specified. When this form is specified, space for the literal must not be allocated in the output message segment supplied by the application program.

(,SCA)
Defines this output field as the system control area which is not displayed on the output device. There can be only one such field in a logical page (LPAGE) and it must be in the first message segment of that page. If no logical pages are defined, only one SCA field can be defined and it must be in the first segment of the output message. This specification is valid only if TYPE=OUTPUT was specified on the previous MSG statement.

MFSDevicePage
DPAGE statement

The DPAGE statement defines a logical page of a device format. This statement can be omitted if none of the message descriptors referring to this device format (FMT) contains LPAGE statements and if no specific device option is required. It is implied if not present.

Unsupported attributes:
- ACTVPID
- COND
- OFTAB
- ORIGIN
- PD
- SELECT
Derived from MFSStatement

163

Private Attributes:
cursor : MFSCursorType
CURSOR attribute

5   Specifies the position of the cursor on a physical page. Multiple cursor
       positions may be required if a logical page or message consists of multiple
       physical pages. The value lll specifies line number, ccc specifies column;
       both lll and ccc must be greater than or equal to 1. The cursor position
       must either be on a defined field or defaulted. The default lll,ccc value for
10   3270 displays is 1,2. For Finance display components, if no cursor
       position is specified, MFS will not position the cursor--the cursor is
       normally placed at the end of the output data on the device. For Finance
       display components, all cursor positioning is absolute, regardless of the
       ORIGIN= parameter specified.

15
       The dfld parameter provides a method for supplying the application
       program with cursor information on input and allowing the application
       program to specify cursor position on output.

20   Recommendation: Use the cursor attribute facility (specify ATTR=YES in
       the MFLD statement) for output cursor positioning.

       The dfld parameter specifies the name of a field containing the cursor
       position. This name may be referenced by an MFLD statement and must
25   not be used as the label of a DFLD statement in this DEV
       definition. The format of this field is two binary halfwords containing line
       and column number, respectively. When this field is referred to by a
       message input descriptor, it will contain the cursor position at message
       entry. If referred to by a message output descriptor, the application
30   program places the desired cursor position into this field as two binary
       halfwords containing line and column, respectively. Binary zeros in the
       named field cause the specified lll,ccc to be used for cursor positioning
       during output. During input, binary zeros in this field indicate that the
       cursor position is not defined. The input MFLD referring to this dfld
35   should be defined within a segment with GRAPHIC=NO specified or
       should use EXIT=(0,2) to convert the binary numbers to decimal.
fill : String
FILL attribute

40   Specifies a fill character for output device fields. Default value for all
       device types except the 3270 display is X'40'; default for the 3270 display
       is PT. For 3270 output when EGCS fields are present, only FILL=PT or
       FILL=NULL should be specified. A FILL=PT erases an output field
       (either a 1- or 2-byte field) only when data is sent to the field, and thus
45   does not erase the DFLD if the application program
       message omits the MFLD.

STL920000075US2

NONE
Must be specified if the fill character from the message output descriptor is to be used to fill the device fields.

X'hh'
Character whose hexadecimal representation is 'hh' will be used to fill the device fields.

C'c'
Character 'c' will be used to fill the device fields.

NULL
Specifies that fields are not to be filled. For devices other than the 3270 display, 'compacted lines' are produced when message data does not fill the device fields.

PT
Specifies that output fields that do not fill the device field (DFLD) are followed by a program tab character to erase data previously in the field; otherwise, this operation is identical to FILL=NULL.

For 3270 display devices, any specification with a value less than X'3F' is changed to X'00' for control characters or to X'40' for other nongraphic characters.

multiplePages : boolean
MULT attribute

Specifies that multiple physical page input messages will be allowed for this DPAGE.

MFSDeviceField
DFLD statement

The DFLD statement defines a field within a device format which is read from or written to a terminal or remote program. Only those areas which are of interest to the IMS or remote application program should be defined. Null space in the format does not need to be defined.

Unsupported attributes:
- SLD
Derived from MFSStatement

Express Mail Label Number EF057996163US

Private Attributes:
attributes : MFSAttributeType
ATTR attribute
extendedAttributes : MFSExtendedAttributeType
EATTR attribute
length : int
LTH attribute

Specifies the length of the field. This operand should be omitted if 'literal' is specified in the positional parameter, in which case the length of literal is used as the field length. Unpredictable output formatting can occur if this operand is used in conjunction with a 'literal' and the two lengths are different. The specified LTH= cannot exceed the physical page size of the device.

The maximum allowable length for all devices except 3270, 3604 display, and DPM with RCDCT=NOSPAN is 8000 characters. For 3270 displays, the maximum length is one less than screen size. For example, for a 480-character display, the maximum length is 479 characters. A length of 0 must not be specified. If SCA and LTH= are both specified, LTH must be 2.

POS= and LTH= do not include the attribute character position reserved for a 3270 display device or a DFLD with ATTR=YES specified. The inclusion of this byte in the design of display/printer formats is necessary because it occupies the screen/printed page position preceding each displayed/printed field even though it is not accessible by an application program.

When defining DFLDs for 3270 printers, a hardware ATTRIBUTE character is not used. Therefore, fields must be defined with a juxtaposition that does not allow for the attribute character unless ATTR=YES is specified. However, for printers defined as 3270P the last column of a print line (based on FEAT=, WIDTH=, or the device default width) cannot be used. The last column of the line is reserved for carriage control operations performed by IMS. Thus, if the print line specifies 120 (FEAT=120) and the DFLD specifies POS=(1,1),LTH=120 then 119 characters are printed on line 1 and one character on line 2.

Detectable fields (DET or IDET) must include four positions in POS and LTH for a 1-byte detection designator character and 3 pad characters, unless the detectable field is the last field on a display line, in which case only one position for the detection designator character is required. The detection designator character must precede field data, and pad characters (if required) follow field data. Detection designator and required pad characters must be supplied by the application program or MFLD literal

166

STL920000075US2

with the field data. Pad characters can also be required in the preceding field on the device.

pen : String
PEN attribute

Specifies a literal to be selected or an operator control function to be performed when this field is detected. If (1) 'literal' is specified, (2) the field is defined as immediately detectable (ATTR= operand), and (3) contains the null or space designator character, the specified literal is placed in the field referred to by the PEN operand of the preceding DEV statement when the field is detected (if no other device fields are modified). If another field on the device is modified, a question mark (?) is provided instead of the literal. Literal length must not exceed 256 bytes.

If (1) a control function is specified, (2) the field is defined as immediately detectable (ATTR= operand), and (3) contains the null or space designator character, the specified control function is performed when the field is detected and no other device fields are modified. If another field on the device is modified, a question mark (?) is provided and the function is not performed. Control functions that can be specified are:

NEXTPP--PAGE ADVANCE
Specifies a request for the next physical page in the current output message. If no output message is in progress, no explicit response is made.

NEXTMSG--MESSAGE ADVANCE
specifies a request to dequeue the output message in progress (if any) and to send the next output message in the queue (if any).

NEXTMSGP--MESSAGE ADVANCE PROTECT
Specifies a request to dequeue the output message in progress (if any), and send the next output message or return an information message indicating that no next message exists.

NEXTLP--NEXT LOGICAL PAGE
Specifies a request for the next logical page of the current message.

ENDMPPI--END MULTIPLE PAGE INPUT
Specifies the end of a multiple physical page input message.

ENDMPPI is valid only if data has been received and will not terminate multiple page input (MPPI) in the absence of data entry.

position : MFSPositionType
POS attribute

167

Defines the first data position of this field in terms of line (lll), column (ccc), and physical page (pp) of the display format. If pp is omitted, 1 is assumed.

For DEV TYPE=3270, 3270-An, or 3270P

lll,ccc,pp
Specifies the line, column, and optionally, the physical page number for an output field. lll, ccc, and pp must be greater than or equal to 1.

For 3270 displays, POS=(1,1) must not be specified. Fields must not be defined such that they wrap from the bottom to the top.

Restriction: On some models of 3270s, the display screen cannot be copied when a field starting on line 1, column 2, has both alphabetic and protect attributes.

value : String

MFSTable
TABLE statement

The TABLE statement initiates and names an operator control table that can be referred to by the OPCTL keyword of the DFLD statement. The TABLE statement, and the IF and TABLEEND statements that follow, must be outside of a MSG or FMT definition.

Unsupported attributes:
- All attributes are supported
Derived from MFSStatement

MFSDeviceDivision
DIV statement

The DIV statement defines device formats within a DIF or DOF. The formats are identified as input, output, or both input and output, and can consist of multiple physical pages. Only one DIV statement per DEV is allowed.

Unsupported attributes:
- RCDCTL
- HDRCTL
- OPTIONS
- OFTAB
- DPN

168

- PRN
- RDPN
- RPRN
Derived from MFSStatement

5

Private Attributes:
type : MFSDescriptorType
    TYPE attribute

10   Describes an input only format (INPUT), an output only format
(OUTPUT), or both (INOUT).

           If DIV TYPE=OUTPUT or TYPE=INPUT is specified, certain DEV
statement keywords are applicable.

15   **compression : MFSCompressionType**
    COMPR attribute

           Requests MFS to remove trailing blanks from short fields, fixed-length
fields, or all fields presented by the application program.

20

MFSIfCondition
    IF statement

25   The IF statement defines an entry in the table named by the previous
TABLE statement. Each IF statement defines a conditional operation and
an associated control or branching function to be performed if the
condition is true.

30   Unsupported attributes:
    - All attributes are supported
Derived from MFSStatement

Private Attributes:
35   **condition : MFSConditionType**
    condition attribute

           Condition has the following format:
           IF (DATA | LENGTH) (=,<,>, ¬,°,°)
40   (literal | data-length) function

           DATA
           Specifies that the conditional operation is to be performed against the data
received from the device for the field.
45

LENGTH
Specifies that the conditional operation is testing the number of characters entered for the field. The size limit for this field is the same as for DFLDs (see "DFLD Statement" in topic 2.5.1.5.8).

=,<,>, ¬,°,°
Specify the conditional relationship that must be true to invoke the specified control function.

'literal'
Is a literal string to which input data is to be compared. The compare is done before the input is translated to upper case. If 'literal' is specified, DATA must be specified in the first operand. If the input data length is not equal to the literal string length, the compare is performed with the smaller length, unless the conditional relationship is ¬ and the data length is zero, in which case the control function is
performed. If the input is in lowercase, the ALPHA statement should be used and the literal coded in lowercase.

data-length
Specifies an integer value to which the number of characters of input data for the field is compared.

NOFUNC
Specifies that conditional function testing is to be terminated.

NEXTPP--PAGE ADVANCE
Specifies a request for the next physical page in the current output message. If no output message is in progress, no explicit response is made.

NEXTMSG--MESSAGE ADVANCE
Specifies a request to dequeue the output message in progress (if any) and to send the next output message in the queue (if any).

NEXTMSGP--MESSAGE ADVANCE PROTECT
Specifies a request to dequeue the output message in progress (if any), and either send the next output message or return an information message indicating that no next message exists.

NEXTLP--NEXT LOGICAL PAGE
Specifies a request for the next logical page of the current message.

PAGEREQ--LOGICAL PAGE REQUEST
Specifies that the second through last characters of input data are to be considered as a logical page request.

170

ENDMPPI--END MULTIPLE PAGE INPUT
Specifies the end of multiple physical page input (this input is the last for the message being created).
action : String

5

MFSPassword
PASSWORD statement

10
The PASSWORD statement identifies one or more fields to be used as an IMS password. When used, the PASSWORD statement and its associated MFLDs must precede the first SEG statement in an input LPAGE or MSG definition. Up to 8 MFLD statements can be specified after the PASSWORD statement but the total password length

15
must not exceed 8 characters. The fill character must be X'40'. For option 1 and 2 messages, the first 8 characters of data after editing are used for the IMS password. For option 3 messages, the data content of the first field after editing is used for the IMS password.

20
A password for 3270 input can also be defined in a DFLD statement. If both password methods are used, the password specified in the MSG definition is used.

Unsupported attributes:
25
 - All attributes are supported
Derived from MFSStatement

MFSDeviceDescriptor
FMT statement

30
The FMT statement initiates and names a format definition that includes one or more device formats differing only in the device type and features specified in the DEV statement. Each device format included in the format definition specifies the layout for data sent to or received from a device or
35
a remote program.

Unsupported attributes:
 - All attributes are supported
Derived from MFSStatement

40

MFSFunctionKeyType

MFSFormatLibrary
This class is designed to duplicate the effects of a FORMATLIB. In other words, it acts as a central point around which MFS sources files are grouped.

This class was introduced to address the problem of MSG and LPAGE statements referring to MSG statements in other source files. Rather to force the user to parse every source file in a given formatlib at once, this class was added to act as a container to MSG pointers. Please see MFSMessagePointer documentation for more information.
Private Attributes:
name : String

MFSMessagePointer
This class is designed to act as a placeholder for MSG statements. Rather than point to actual MSG statements from the NXT attribute (nextMessage relationship), MSG and LPAGE statements will point to an instance of this class.

A new instance of this class will be created when a MSG or LPAGE statement points to a MSG statement that is not represented in this particular FORMATLIB. A new instance will also be created when an MSG statement is parsed, if that statement is not already represented here.

7. Illustrative Applications of the Common Application Metamodel and System

Various complex transaction, occurring across a plurality of individual platforms require the seamlessness and transparency of the Common Application Metamodel. These

5   transactions include "rich" transactions, high level group ware, and financial transactions.

FIGURE 40 illustrates a simplified network configuration for a "rich" transaction where, for example, an order is entered at a terminal, and is passed to and through a Web server to a manufacturer's application server. The manufacturer's application server searches

10   through it's own database server, as well as its vendors' dissimilar and incompatible database servers and databases, transparently connected by the connectors described herein, querying for statuses, prices, and delivery dates, of components, and placing orders for needed components to satisfy the order.

15   Strictly for purposes of illustration and not limitation, a rich transaction is illustrated with the purchase of an automobile, from configuring and ordering the new automobile through financing the automobile, collecting the elements and components the new automobile, assembling the automobile, and delivering it to the customer. In configuring the automobile, consider the inclusion of, e.g., a traction control module, which may

20   require the inclusion of one sub-set of engines, while precluding the inclusion of another sub-set of engines, for example, for technical or performance reasons. Similarly, the selection of one color may preclude the selection of certain upholstery combinations, for example, for reasons of inventory or availability. Of course, if you don't select an engine and a transmission, you don't have an automobile. Certain choices must be made. The

25   problem is one of "If you pick `X`, you must also pick `Y` and `Z`, but if you pick `Y`, you can not get `A` or `B`, and you have already selected `A`." That is, selection of one component or sub-system may remove some previously selected components or sub-systems from the system. After configuring the car, frequently based on the availability of selected elements in the supply pipeline, the order is sent to the manufacturer's server

30   for fulfillment, including manufacturing scheduling. The manufacturer would query the vendors in the supply chain, for example, a transmission vendor, who would, in turn,

STL920000075US2

query controller vendors, gear vendors, housing vendors, hydraulic conduit vendors, and the like. These vendors would, in turn query their sub-vendors.

Using the connector method and system, the dealer and customer would configure and order the car at a terminal 3901. The configuration and order entry would be sent to the manufacturer's server 3911. The manufacturer's server queries the servers 3921, 3931, and 3441, (where server 3921 could be the server for the manufacturer's in house components business and for its purchasing function) or its direct vendors, who in turn query third sub-vendors, 3923, 3933, and 3933. The queries could be in the form of "fill in the blank" SQL queries, subject to access authorizations. The sub-vendor servers, 3923, 3933, and 3443 specialized views to the vendor's servers 3921, 3931, 3441, as clients, which in turn would present specialized views to the manufacturer's server 3911 as a client. The data returned to the manufacturer's server 3911 could be optimized with optimization and production scheduling applications, to present a serial number and delivery date to the buyer at the dealer's server.

A further application of the connectors of the present invention is in connection with groupware, and especially linking "islands of groupware" together. "Groupware" is a broad term applied to technology that is designed to facilitate the work of groups. Groupware technology may be used to communicate, cooperate, coordinate, solve problems, compete, or negotiate. A Groupware suite of applications is comprised of programs that help people work together collectively, even if located remotely from each other. Groupware services can include the sharing of calendars, collective writing, e-mail handling, shared database access, electronic meetings, video conferencing, and other activities.

FIGURE 41 illustrates a group ware session spread across multiple group ware applications running on multiple, disparate platforms, and connected by the connectors described herein. Specifically illustrated are two groupware systems 4010 and 4020. Each system contains e-mail enables applications, 4013 and 4023, such as e-mail, schedule/calendar, word processor, spread sheet, graphics, and CTI (computer telephony

integration). These are supported by message API's 4015, 4025 and operating systems, 4017 and 4027, and local groupware servers 4011 and 4021. Each of the local groupware servers, 4011 and 4021, has a connector of the present invention, an e-mail server, an e-mail data base, a directory server, and a replication database. The two groupware servers 5   4011 and 4021 communicate over a telecommunications medium, as the Net, a LAN, a WAN, or even the PSTN.

E-mail is by far the most common and basic groupware application. While the basic technology is designed to pass simple messages between people, even relatively simple e-10   mail systems today typically include features for forwarding messages, filing messages, creating mailing groups, and attaching files with a message. Other features that have been explored include content based sorting and processing of messages, content based routing of messages, and structured communication (messages requiring certain information).

15   Workflow systems are another element of groupware. Work flow systems allow documents to be routed through organizations through a relatively-fixed process. A simple example of a workflow application is an expense report in an organization: an employee enters an expense report and submits it, a copy is archived then routed to the employee's manager for approval, the manager receives the document, electronically 20   approves it and sends it on and the expense is registered to the group's account and forwarded to the accounting department for payment. Workflow systems may provide features such as routing, development of forms, and support for differing roles and privileges.

25   Hypertext is a system for linking text documents to each other, with the Web being an obvious example. However, whenever multiple people author and link documents, the system becomes group work, constantly evolving and responding to others' work. Another common multi-user feature in hypertext (that is not found on the Web) is allowing any user to create links from any page, so that others can be informed when 30   there are relevant links that the original author was unaware of.

Group calendaring is another aspect of groupware and facilitates scheduling, project management, and coordination among many people, and may provide support for scheduling equipment as well. Typical features detect when schedules conflict or find meeting times that will work for everyone. Group calendars also help to locate people.

5

Collaborative writing systems may provide both realtime support and non-realtime support. Word processors may provide asynchronous support by showing authorship and by allowing users to track changes and make annotations to documents. Authors collaborating on a document may also be given tools to help plan and coordinate the

10 authoring process, such as methods for locking parts of the document or linking separately-authored documents. Synchronous support allows authors to see each other's changes as they make them, and usually needs to provide an additional communication channel to the authors as they work.

15 Group may be synchronous or real time, such as shared whiteboards that allow two or more people to view and draw on a shared drawing surface even from different locations. This can be used, for instance, during a phone call, where each person can jot down notes (e.g. a name, phone number, or map) or to work collaboratively on a visual problem. Most shared whiteboards are designed for informal conversation, but they may also serve

20 structured communications or more sophisticated drawing tasks, such as collaborative graphic design, publishing, or engineering applications. Shared whiteboards can indicate where each person is drawing or pointing by showing telepointers, which are color-coded or labeled to identify each person.

25 A further aspect of groupware is video conferencing. Video conferencing systems allow two-way or multi-way calling with live video, essentially a telephone system with an additional visual component, with time stamping for coordination.

Decision support systems are another aspect of groupware and are designed to facilitate

30 groups in decision-making. They provide tools for brainstorming, critiquing ideas, putting weights and probabilities on events and alternatives, and voting. Such systems

enable presumably more rational and evenhanded decisions. Primarily designed to facilitate meetings, they encourage equal participation by, for instance, providing anonymity or enforcing turn-taking.

5   Multi-player games have always been reasonably common in arcades, but are becoming quite common on the Internet. Many of the earliest electronic arcade games were multi-user, for example, Pong, Space Wars, and car racing games. Games are the prototypical example of multi-user situations "non-cooperative", though even competitive games require players to cooperate in following the rules of the game. Games can be enhanced

10   by other communication media, such as chat or video systems.

Some product examples of groupware include Lotus Notes and Microsoft Exchange, both of which facilitate calendar sharing, e-mail handling, and the replication of files across a distributed system so that all users can view the same information.

15

What makes the connectors of the present invention particularly attractive for groupware applications is the diversity of groupware offerings and group server architectures, implementations, and platforms. The connector of the invention can act as a front end or gateway to the groupware server.

20

FIGURE 42 illustrates a commercial transaction where real goods are shipped from a seller to a buyer, and various forms of electronic payment and secured electronic payment are used by the buyer to pay the seller, with banks and financial institutions connected through the connectors described herein. Specifically, a merchant or manufacturer 4101

25   sells a product to a customer 4103 that he has no "history" with. The product is shipped 4605. However, the buyer 4103 does not wish to be parted from his money until the goods are received, inspected, approved, and "accepted", while the seller 4101 does not want to give up control of the goods until he has been paid. This fundamental commercial conflict has led to various paradigms, most involving hard copy "near moneys" or

30   instruments of one form or another. Today, the financial transactions are most frequently those involving electronic fund transfers, and electronic versions of notes, instruments,

negotiable instruments, documentary drafts, payment orders, letters of credit, warehouse receipts, delivery orders, bills of lading, including claims on goods, that is, documents of title that purport to transfer title or physical custody of goods to the bearer or to a named person, and security interests in goods. Typically, the customer 4103 executes an

5   instrument in favor of the seller 4101, directing the buyer's bank 4121 to pay buyer's money to the seller 4101 through seller's bank 4125. Normally, this is a simple electronic transaction between buyers and sellers who have dealt with each other before, dealing through banks or financial intermediaries who have dealt with each other before, and who are using the same or compatible software applications. However, in the

10   extraordinary case where these preconditions are not satisfied, the connectors of the invention facilitate the electronic, bank-to-bank, side of the transaction.

While the invention has been described and illustrated with respect to applications having a single level of application program interfaces or converters, it is, of course, to be

15   understood that such application program interfaces or converters may be present at various levels in the processing hierarchy, for example between Web Clients and Web servers, between web servers and application servers, between application servers and database servers, and between application servers or database servers or both and various specialized repositories.

20

It is also to be understood, that while the invention has been described and illustrated with respect to certain preferred embodiments and exemplification having individual clients and individual servers, there may be multiple clients, multiple servers, and applications that function as both clients and servers, as exemplified by groupware

25   applications, and there might be multiple parallel lines and/or multiple hierarchical levels of application servers, data servers, and databases, as in systems for rich transactions.

While the invention has been described with respect to certain preferred embodiments and exemplifications, it is not intended to limit the scope of the invention thereby, but

30   solely by the claims appended hereto.
